17 **Abstract**

18 Angiotensin-converting enzyme 2 (ACE2) is a binding target of severe acute respiratory syndrome
19 coronavirus 2 (SARS-CoV-2) spike protein. An ACE2-like enzyme, such as bacterial M32-carboxypeptidase
20 (M32-CAP), is assumed to be a potential therapeutic candidate for coronavirus disease 2019 (COVID-19). Here,
21 we screened bacteria with an ACE2-like enzyme activity from Japanese fermented food and dietary products using
22 the fluorogenic substrate for rapid screening. The strain showing the highest activity, *Enterobacter* sp. 200527-13,
23 produced an enzyme with the same hydrolytic activity as ACE2 on Angiotensin II (Ang II). The enzymatic analysis
24 using the heterologously-expressed enzyme in *E. coli* revealed that the enzyme catalyzes the same reaction with
25 that of ACE2, Ang II hydrolysis to Ang 1-7 and phenylalanine. The gene sequence information showed that the
26 enzyme belongs to the M32-CAP family. These results suggested that the selected enzyme, M32-CAP (EntCP),
27 from *Enterobacter* sp. 200527-13 was identified as an ACE2-like enzyme.

28

29 **Keywords:** ACE2, *Enterobacter* sp., M32-carboxypeptidase, SARS-CoV-2.

30

31 **Introduction**

32 Driven by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, coronavirus
33 disease 2019 (COVID-19) has caused major problems for healthcare systems globally. On October 27, 2022,
34 global infections were reported to be over 626 million with the number of deaths reaching 6 million (WHO, 2022).
35 These numbers will continue to increase due to the rapid mutation rate of the virus, challenging researchers to
36 find a specific vaccine or antiviral treatment (Lei et al., 2020). SARS-CoV-2 associates with the human
37 angiotensin-converting enzyme 2 (ACE2) to enter into cells. ACE2 is a carboxypeptidase that attacks Angiotensin
38 II (Ang II), degrading it into Angiotensin 1-7 (Ang 1-7) in the renin-angiotensin system (RAS) (Romero et al.,
39 2015). Together with its homologs (the angiotensin-converting enzyme, ACE), ACE2 maintains homeostasis in
40 cardiorenal activity and cell protection and proliferation. ACE2 is abundantly expressed in the lungs and intestinal
41 epithelium of the esophagus, ileum, and colon epithelial cells (Salamanna et al., 2020). ACE activity produces
42 Ang II by cleaving Ang I, with Ang II blood accumulation being associated with hypertension, accelerated
43 thrombosis, and endothelial injury (Samavati et al, 2020). Therefore, a balance between ACE and ACE2 must be
44 maintained.

45 SARS-CoV-2 has a surface-anchored spike (S) glycoprotein composed of the S1 domain responsible for
46 human receptor binding through the receptor-binding domain (RBD) site and the S2 domain that mediates
47 membrane fusion (Chen et al., 2021). The interaction of RBD with the human ACE2 drives ACE2 loss of function,
48 leading to the accumulation of Ang II in the lung tissue and inflammatory lesions in the respiratory tree (alveolar
49 wall thickening, edema, infiltration of inflammatory cells, and bleeding) (Verdecchia et al., 2020). Acute
50 respiratory distress syndrome (ARDS) is commonly found in COVID-19 patients. Additionally, the accumulation
51 of Ang II results in cardiac injury as a consequence of myocardial inflammation, oxidative stress, and myocyte
52 apoptosis (Ravichandran et al., 2021). Hence, there is a need for a new approach to handle the accumulation of
53 Ang II in patients with COVID-19 and those not.

54 The recombinant human ACE2 (rhACE2) protein is currently under clinical trials to treat patients with
55 ARDS. However, rhACE2 may be unfavorable for drug development and the medical economy because it is
56 glycosylated. Consequently, rhACE2 expression in mammalian or insect cell lines is time consuming and
57 expensive. Another alternative for therapeutic development is the use of engineered bacterial proteins. One
58 promising protein is the bacterial M32 family of carboxypeptidases (M32-CAP) containing the HEXXH motif
59 within its active site. The structural analysis and crystal structure of three microbial strains—M32-CAP from
60 *Thermus aquaticus* (TaqCP), *Pyrococcus furiosus* (PfuCP), and *Bacillus subtilis* (BsuCP)—have been reported in

61 the MEROPS database (<http://merops.sanger.ac.uk/>) (Minato et al., 2020; Arndt et al., 2002; Lee et al., 2009).
62 Among the three different microbes, only BsuCP is a protein structurally related to human ACE2 with the position
63 of the key amino acid constituting the catalytic site and substrate-binding region (Arg273/348, His345/234,
64 His505/408, and Tyr515/420 in ACE2/BsuCP), which are almost identical between the two proteins, suggesting
65 that BsuCP may have a similar substrate preference to ACE2. A study by Minato et al. (2020) found that M32-
66 CAP from *Paenibacillus* sp. B38 (B38-CAP) has ACE2-like activity in mammals under physiological conditions,
67 which could improve hypertension and heart failure. This work was continued by Yamaguchi et al. (2021) and
68 resulted in the relief of lung edema in SARS-CoV-2-infected hamsters. This uncovers a new path to improve the
69 prognosis of similarly infected humans.

70 Food-related microorganisms have been utilized for many years, the most impressive of which is in
71 health-inducing products, such as traditional fermented food. Food-fermenting microbes can improve nutritional
72 value and induce immune responses during pathogen infections (Surono, 2016; Muhialdin et al, 2021). A study
73 conducted by Lee et al. (2006) used *Lactobacillus casei* as a host vector that expresses the SARS-CoV spike on
74 the extracellular membrane surface, showing neutralizing antibody activity in mice on day 21 after immunization.
75 Hence, food-related microorganisms are promised to be potent candidates providing ACE2-like enzyme useful
76 for COVID-19 therapy, which can inhibit human ACE2 and SARS-CoV-2 binding.

77 Here, we show that M32-CAP can cleave human ACE2 substrates. This protein, defined as EntCP, is
78 found within the genome of the *Enterobacter* sp. isolated from garlic. EntCP shows hydrolytic activity toward the
79 fluorogenic substrate 2-(methylamino)benzoyl (Nma)-His-Pro-Lys[2,4-dinitrophenyl (Dnp)] and Ang II.

80

81 **Methods**

82 **Materials**

83 Angiotensin II was purchased from Bachem AG (Bubendorf, Switzerland); ACE2 was purchased from
84 Sino Biological, Inc. (Hong Kong, China); and Nma-His-Pro-Lys(Dnp) was purchased from the Peptide Institute,
85 Inc. (Osaka, Japan).

86

87 **ACE2-like enzyme bacteria screening**

88 Different types of Japanese fermented food and dietary products were collected, of which 12 were
89 commercially purchased from different convenience stores. We successfully isolated 61 bacteria from all of them
90 by growing them in a MRS medium (Becton, Dickinson and Company, New Jersey, United States of America).

91 The MRS medium is composed of 1 % (w/v) proteose peptone No. 3, 1 % (w/v) beef extract, 0.5 % (w/v) yeast
92 extract, 2 % (w/v) dextrose, 0.1 % (w/v) polysorbate 80, 0.2 % (w/v) ammonium citrate, 0.5 % (w/v) sodium
93 acetate, 0.01 % (w/v) magnesium sulfate, 0.005 % (w/v) manganese sulfate, and 0.2 % (w/v) dipotassium
94 phosphate. We also added 16 additional bacterial isolates, including *Periweissella beninensis* JCM 18047,
95 *Weissella minor* JCM 1168, *W. diestrammenae* JCM 18559, *W. kandleri* JCM 5817, *W. koreensis* JCM 11263, *W.*
96 *oryzae* JCM 18191, *W. halotolerans* JCM 1114, *W. viridescens* JCM 1174, *W. hellenica* NBRC 15553, *W. cibaria*
97 NBRC 106073, *W. soli* NBRC 106074, *W. confuse* NBRC 106469, *W. paramesenteroides* NBRC 109620, *W.*
98 *thailandensis* NBRC 109621, *W. cryptocercid* NBRC 113066, and *W. muntiaci* NBRC 113537. Two bacterial
99 strains, namely, *Bacillus subtilis* NBRC 3022 and *B. amyloliquefasciens* NBRC 13719, served as positive controls
100 for M32-CAP gene content. All bacterial strains used in this study were grown in 500 mL MRS medium. Each
101 bacterial cell was harvested via centrifugation at $12,000 \times g$ (8,000 rpm) for 20 min at 4 °C using high-speed
102 refrigerated centrifuge CR21N (Eppendorf Himac Technologies Co., Ltd., Ibaraki, Japan) equipped with R10A
103 rotor. The supernatant was discarded, and the pellet was weighed to obtain a cell-free extract (CFE) and rehydrated
104 using an assay buffer (pH 6.5) containing 50 mM 2-morpholinoethanesulfonic acid (MES), 300 mM NaCl, and
105 10 μM ZnCl_2 with volumes double that of the pellet weight. The pellet was placed in a suspension buffer fixed at
106 30–70 % volume of the multi-bead tube ST-0250 (Yasui Kikai, Osaka, Japan). YGB01 glass beads (Yasui Kikai)
107 were added into a multi-bead tube containing cell suspension at a ratio of 1:1 (w/v), mixed by vortexing, and
108 stored at 4 °C. A Multi-Beads Shocker instrument (Yasui Kikai) was used with the following setup: 2,500 rpm
109 speed, 60 s on time, 60 s off time, and 3–6 cycles. The sample was then centrifuged at $20,400 \times g$ (15,000 rpm) at
110 4 °C for 5 min using high speed refrigerated micro centrifuge MX-307 (Tomy Seiko Co., Ltd., Tokyo, Japan) to
111 collect CFE for further investigation. Rapid ACE2-like enzyme screening was performed using Nma-His-Pro-
112 Lys(Dnp). All CFE was concentrated by centrifugation at 5,280 rpm at 4 °C for 10 min by an ultrafiltration
113 membrane 10,000 MWCO. Concentrated CFE was then dissolved in assay buffer at a ratio of 1:3 (v/v), and CFE
114 hydrolysis activity was determined in dark microtiter plates at room temperature. The reaction mixture contained
115 40 μL assay buffer and 10 μL Nma-His-Pro-Lys(Dnp) (final concentration: 0.1 mM). The reaction was initiated
116 by adding 150 μL CFE or 250 $\mu\text{g/mL}$ ACE2 (final concentration: 1.3 $\mu\text{g/mL}$) as a control, so that the total reaction
117 volume was 200 μL . The emission and excitation wavelength of the fluorescence were 440 nm and 340 nm,
118 respectively. Fluorescence intensity was recorded every 15 min for 4 h of incubation.

119

120 **Determination of bacterial CFE activity toward Ang II**

121 Bacterial CFE exhibiting hydrolytic activity against Nma-His-Pro-Lys(Dnp) were further evaluated
122 using Ang II as a native substrate of human ACE2. To determine the hydrolysis products produced by this enzyme
123 within the CFE, peak detection and elution from the HPLC column were used. The reaction was performed at
124 room temperature in a 100- μ L total volume mixture containing 40 μ L assay buffer, 10 μ L of 2 mM Ang II (final
125 concentration: 0.1 mM), and 50 μ L CFE or 250 μ g/mL ACE2. The mixture was incubated for 5 and 30 min, and
126 the reaction was quenched by the addition of 0.5 M EDTA. A reaction sample (10 μ L) was injected into the HPLC
127 system. Substrate and peptides produced were resolved by a YMC-Pack ODS-A 4.6 \times 300-mm (AA12S05-
128 3046WT) column using 10 % acetonitrile (v/v) with 0.1 % acetic acid (v/v) and 40 % acetonitrile (v/v) with 0.1 %
129 acetic acid (v/v) as the mobile phases A and B, respectively. The gradient elution scheme was performed as
130 follows: 0–10 min, 100 % of mobile phase A; 10–25 min, linear gradient from 0–100 % of mobile phase B; 25–
131 35 min, 100 % of mobile phase B; 35–40 min, linear gradient from 100 % of mobile phase A; and a 0.8 mL/min
132 flow rate. Both the substrate and peptide products were detected by measuring absorbance at 215 nm.

133 The hydrolytic activity of bacterial CFE against Ang II was also determined using LC-MS to detect any
134 amino acid released during the enzymatic reaction based on its molecular weight. The LC-MS system was
135 equipped with the same column and elution buffer. The gradient elution scheme was performed as follows: 0–40
136 min, 100 % of mobile phase A; 40–100 min, linear gradient from 0–100 % of mobile phase B; 100–140 min,
137 100 % of mobile phase B; 140–160 min, linear gradient from 100 % of mobile phase A; and 0.3 mL/min flow rate.
138 Detection was performed using negative-mode electrospray ionization (ESI). The MS conditions were as follows:
139 interface temperature, 350 $^{\circ}$ C; DL temperature, 250 $^{\circ}$ C; nebulizing gas flow 1.5 L/min; heat block temperature,
140 200 $^{\circ}$ C; and drying gas flow, 10 L/min.

141

142 **Bacterial CFE protein purification**

143 Protein purification was conducted to isolate the expected protein of interest within bacterial CFE using
144 the ÄKTA explorer fast protein liquid chromatography system (Cytiva, Tokyo, Japan). The first purification step
145 was done using HiPrepTM Q XL 16/10 column (Cytiva, Tokyo, Japan). The binding buffer was prepared by mixing
146 20 mM MES in ultrapure water at pH 6.5, whereas the elution buffer consisted of 1 M NaCl and 20 mM MES in
147 ultrapure water at pH 6.5. A fraction of 190 μ L was collected and assayed for Nma-His-Pro-Lys(Dnp) hydrolytic
148 activity. The highest activity of the protein that exhibited ACE2-like enzyme activity was pooled and subjected to
149 a second purification step using a SuperdexTM 200 Increase 10/300 GL column (Cytiva). Equilibration and elution
150 were performed at room temperature using 150 mM MES in ultrapure water at a pH of 6.5. Approximately 50 μ L

151 of each fraction was rapidly screened using Nma-His-Pro-Lys(Dnp). The fractions exhibiting ACE2-like enzyme
152 activity were analyzed by sodium dodecyl-sulfate polyacrylamide gel electrophoresis (SDS-PAGE) with a
153 subsequent transfer to a PVDF membrane (for electroblotting using HorizeBLOT). The transferred protein was
154 loaded into the protein sequencer to determine the amino acid sequences through Edman degradation. The amino
155 acid sequences were read and searched in the NCBI database using BLASTP.

156

157 **Draft genome sequence of the selected strain 200527-13**

158 The genome was purified from the selected strain 200527-13 by DNeasy® Blood & Tissue Kit (Qiagen,
159 Venlo, Netherlands). Next-generation sequencing of the strain was performed in the Bioengineering Lab. Co., Ltd.
160 (Kanagawa, Japan). The assembled genome was annotated using the DDBJ Fast Annotation and Submission Tool
161 (DFAST). The accession numbers are BSCM01000001–BSCM01000033.

162

163 **Recombinant ACE2-like enzyme**

164 The bacterial isolate, expected to have ACE2-like enzyme gene content based on protein sequencing
165 results, underwent genomic DNA extraction. The DNA of gene interest within the bacterial genomic DNA was
166 isolated by PCR for cloning purposes. Double digestion of the pET21b plasmid was carried out using a mixture
167 (50 µL) of 10 U Nde I (Takara), 10 U Xho I, pET21b DNA ≤ 1 µg, and 1 × H buffer. The reaction mixture was
168 then incubated for 1 h at 37 °C. The forward and reverse primers used to amplify EntCP gene were purchased
169 from Hokkaido System Science Co., Ltd. (Hokkaido, Japan). The forward primer sequence consisted of GTT
170 TAA CTT TAA GAA GGA GAT ATA CAT ATG AGC GAA AAC AGC CAC TA. The reverse primer used in
171 this study was CGG ATC TCA GTG GTG GTG GTG GTG CTC CAG ATA ACG GGA CGT CAA AT.
172 EntCP was amplified by PCR using primers and Tks Gflex DNA Polymerase (Takara Bio Inc., Shiga, Japan). The
173 digested pET21b plasmid and PCR products were purified by electrophoresis using agarose gel and FastGene
174 Gel/PCR Extraction Kit (Nippon Genetics Co., Ltd., Tokyo, Japan). The purified PCR product was inserted into
175 pET21b by incubating the reaction mixture of 4 µL purified digested pET21b, 4 µL purified PCR product, and 2
176 µL 5 × In-Fusion HD Enzyme Premix (Takara Bio Inc., Shiga, Japan) for 15 min at 50 °C. The resulting plasmid,
177 pET21b-EntCP, was transformed into *Escherichia coli* DH5α competent cells as a cloning host before being
178 transformed into the expression host, *E. coli* Rosetta 2 (DE3), which supplies tRNA for rare codons.
179 Transformants were selected by growing them on a Luria-Bertani medium containing ampicillin (50 µm/mL) and
180 chloramphenicol (25 µg/mL). EntCP gene expression within transformant cells was induced by adding isopropyl

181 β -D-thiogalactopyranoside (final concentration of 1 mM) to the culture media. The cells were harvested by
182 centrifugation and disrupted to obtain CFE. Hydrolytic activity was confirmed using Nma-His-Pro-Lys(Dnp), as
183 previously mentioned. Protein expression was visualized using SDS-PAGE before purification. Protein
184 purification was performed using the HisTrap™ column (Cytiva) for affinity chromatography. The CFE was
185 equilibrated with 50 mM imidazole and 20 mM MES in 500 mL ultrapure water at pH 6.5. Proteins were eluted
186 using 250 mM imidazole and 20 mM MES in ultrapure water at pH 6.5. The purified protein fraction was then
187 subjected to LC-MS analysis.

188

189 **Accession numbers**

190 The accession number of the ACE2-like enzyme (EntCP) from the *Enterobacter* sp. 200527-13 was
191 registered as LC739013. Accession numbers of genomes of the *Enterobacter* sp. 200527-13 were registered as
192 BSCM01000001-BSCM01000033.

193

194 **Results**

195 **Screening of ACE2-like enzyme in food-related microorganisms**

196 Nma-His-Pro-Lys(Dnp) was used for rapid screening to find an ACE2-like enzyme, as previously
197 described by Takahashi et al. (2015). Among all bacterial cells tested, only five isolates (200527-1, 200527-5,
198 200527-14, 200527-13, and 191211-2) exhibited Nma-His-Pro-Lys(Dnp)-hydrolyzing activity (Figure 1). Among
199 these five, the isolate 200527-13 (isolated from garlic) showed the highest hydrolysis activity, as shown in Figure
200 1. The CFE of both *B. cereus* NBRC 3022 and *B. amyloliquefasciens* NBRC 13719 as a positive control showed
201 much lower hydrolytic activity than the others. To confirm the presence of an ACE2-like enzyme within the strain
202 200527-13, its CFE was challenged with the 2 mM Ang II peptide as a native human ACE2 substrate. The reaction
203 products generated after incubating Ang II with the CFE of the strain 200527-13 were compared to those generated
204 by the three different positive controls. After 5 h of incubation of 2 mM Ang II with 250 μ g/mL ACE2, the peak
205 of Ang 1-7 appeared, and the peak of Ang II disappeared (Figure S1(A)). On the other hand, Ang 1-7 was not
206 detected in the reaction with the CFE of either *B. cereus* or *B. amyloliquefasciens*, although no Ang II peak was
207 detected (Figure S1(A)). The CFE of the strain 200527-13 can digest the Ang II, however, no Ang 1-7 peptide
208 peak was observed (Figure S1(B)). To investigate the mode of action of bacterial enzymes showing different
209 results with that of human ACE2, LC-MS analysis and successive enzyme purification were performed.

210

211 **Identification of an ACE2-like enzyme in the strain 200527-13**

212 The hydrolysis of Ang II peptide (DRVYIHPF, m/z 1046.5 on positive mode ($[M + H]^+$) LC-MS
213 analysis) by human ACE2 resulted in generations of Ang 1-7 (DRVYIHP, m/z 899.5) and phenylalanine (F, m/z
214 166.1) (Figure S2(A)). The CFE of *B. subtilis* NBRC 3022 also showed hydrolytic activity similar to that of human
215 ACE2, as reported by Minato et al. (2020) (Figure S2(B)). However, with the CFE of the strain 200527-13 no
216 accumulation of Ang 1-7 was observed; indicating that the CFE contained Ang 1-7 degrading enzymes together
217 with an ACE2-like enzyme. Then, we proceeded to enzyme purification from the CFE of the strain 200527-13.

218 Through two column chromatography steps using HiPrep™ Q XL 16/10 column and Superdex 200
219 Increase 10/300 GL column with the activity assay using the fluorogenic substrate, the protein was purified by
220 approximately 1,000-fold with 6 % yield from the CFE (Table 1) . Based on the comparison of protein profile on
221 SDS-PAGE and the activity profile of each fraction obtained by column chromatography, the protein with a
222 molecular weight of 50 kDa was assumed to be the target protein (Figure 2(A-B)). Therefore, the 50 kDa protein
223 in the fraction No. 12 was applied to Edman degradation for protein sequencing. We detected a NH₂-terminal
224 amino acid sequence of SENSXYQQLTXXQRLSXX. By comparing the amino acid sequence to the database
225 BlastP NCBI, the protein was found to show 82.4 % identity with M32-CAP from the *Enterobacter* sp. The whole
226 gene sequence of the purified enzyme, EntCP (accession number: LC739013), was obtained from the genome
227 data of the *Enterobacter* sp. 200527-13 (BSCM01000001-BSCM01000033).

228

229 **Classification of EntCP in comparison with proteins in the M32-CAP family**

230 To verify the protein family that EntCP belongs to, we conducted sequence alignment analysis against
231 other proteins. Through multiple sequence alignment using the MUSCLE 3.8 tool, EntCP was noted to have the
232 signature zinc-binding motif HEXXH of the M32-CAP family (in solid line square) in Figure 3(A)). This motif is
233 conserved among selected proteins, including carboxypeptidase from *Paenibacillus* sp. B38 (B38-CAP, NCBI
234 LC406946), *Fervidobacterium islandicum* (FisCP, PDB 5E3X, and NCBI WP_033190981.1), *Pyrococcus*
235 *furiosus* (PfuCP, PDB 1K9X, and NCBI WP_011011573.1), *Bacillus subtilis* (BsuCP, PDB 3HQ2, and NCBI
236 WP_004398513.1), *Deinococcus radiodurans* (DnrCP, PDB 5GIV, and WP_010889049.1), and *Thermus*
237 *thermophilus* (TthCP, PDB 3HOA, and NCBI WP_011174078.1), while the DsbA (PDB 1BED, and NCBI
238 WP_002050636.1) from *Vibrio cholerae* serves as an outgroup. In addition, EntCP revealed to have five other
239 conserved motifs, including HPF, DXRXT, HESQ, IRXXAD, and GXXQDXHW (in dashed line square) that
240 further define its protein family. Regarding the phylogenetic tree, EntCP appears in a separate branch from the

241 other homologous proteins (Figure 3(B)). EntCP has 75 % and 74 % similarity to B38-CAP and BsuCP,
242 respectively.

243

244 **Hydrolysis activity of recombinant EntCP**

245 Recombinant EntCP was successfully expressed in *E. coli* Rosetta 2 (DE3) (Figure 4(A)). The
246 recombinant protein was purified from the crude CFE (Figure 4(B)). The purified recombinant EntCP showed the
247 activity against the fluorogenic substrate with a value of 495×10^3 relative fluorescence units (RFU)·sec⁻¹·L·mg⁻¹
248 protein. Ang 1-7 and phenylalanine were also produced during the incubation of the purified recombinant EntCP
249 with Ang II, as revealed by LC-MS analysis (Figure 4(C)).

250

251 **Discussion**

252 The food-related microorganisms used here were chosen because of their greater ability to promote and
253 maintain our health. This not only reduces intestinal inflammatory disease but also enhances the function of the
254 innate immune system, specifically natural killer cells (NKC), which act as the first line of defense against
255 bacterial or viral infections and tumor formation (Muhialdin et al., 2021). An ACE2-like enzyme within food-
256 related microorganisms was screened based on the ability of each CFE to cleave Nma-His-Pro-Lys(Dnp). Dnp
257 bound to the amino acid lysine serves as a fluorescence quencher for Nma. Once ACE2 recognizes and cleaves
258 lysine-Dnp within the carboxy-terminal site, the fluorophore is released and detected by a spectrofluorometer, as
259 illustrated in Figure 5(A-B) (Takahashi et al., 2015). Therefore, Nma-His-Pro-Lys(Dnp) was used as a prompt
260 screening method here to determine the ACE2-like enzyme activity among several bacterial isolates. This was
261 then confirmed by incubating the bacterial CFE candidate with Ang II. Among all the bacteria tested, the highest
262 fluorogenic activity was found with the CFE of the strain 200527-13. The strain was considered to contain more
263 than one protein involved in Ang II degradation. While, this study only focused on proteins that exhibit proteolytic
264 activity similar to that of human ACE2. Through purification, we succeeded in isolating M32-CAP from the
265 *Enterobacter* sp. and named it EntCP. This protein is quite similar to the one used in the study conducted by
266 Minato et al. (2020), who described B38-CAP isolated from the *Paenibacillus* sp. B38 and BsuCP from *Bacillus*
267 *subtilis* (Lee et al., 2009) by having the conserved motif shown in Figure 3(A). Our ACE2-like enzyme was
268 isolated from the opportunistic pathogen *Enterobacter* sp. However, the *Enterobacter* sp. has also been exploited
269 to produce fermented wheat flour, which improves the nutritional value of food (Manguntungi et al., 2020; Nagano
270 et al., 2003).

271 Recombinant EntCP, with a molecular weight of 50 kDa, showed a branch close to BsuCP in the
272 phylogenetic tree. Other M32-CAP including B38-CAP and ChtCP, have similar molecular weights (Minato et al.,
273 2020; Fernandes et al., 2021). BsuCP was the first M32-CAP that was structurally similar to human ACE2, as
274 elucidated by performing a superimposition. By having a similar structure, the positions of the substrate- and
275 metal-binding residues match each other (Minato et al., 2020). Arg273, situated within the ACE2 active site, plays
276 an important role in the formation of a salt bridge with a C-terminal substrate, while His505, His345, and Tyr515
277 are involved in the binding or activity of metal ions (Biswas et al., 2020). These residues are equivalent to Arg348,
278 His408, His234, and Tyr420 in BsuCP (Lee et al., 2009). Sequence alignment revealed that all residues were
279 conserved within EntCP at Arg346, His407, His234, and Tyr455. We also found the conservation of a signature
280 metal-binding motif, namely, HEXXH, and another motif that is responsible for substrate binding or metal ion
281 binding (Lee et al., 2006). Based on the conservation of key residues that constitute the protein structure of both
282 EntCP and human ACE2, we suggest EntCP derived from food-related microorganisms as an alternative tool to
283 develop human ACE2 “receptor mimics” inhibiting SARS-CoV-2 infection. In addition, this protein is promising
284 in drug development to treat Ang II-related diseases.

285

286 **Conclusions**

287 Based on the hydrolysis activity against fluorogenic substrate and Ang II, the food-related bacterial strain,
288 *Enterobacter* sp. 200527-13, was considered to contain more than one active enzyme involved in Ang II
289 degradation. One of the most effective enzymes found was defined as EntCP, which has a molecular weight of 50
290 kDa (similar to those of BsuCP, B38-CAP, and ChtCP) and catalyzed the same hydrolytic reaction with ACE2 on
291 Ang II, generating Ang 1-7 and phenylalanine. By having a similar key residue and protein structure with human
292 ACE2, EntCP appears to be a potential therapeutic candidate against SARS-CoV-2 infection. It is predicted to not
293 only block viral entry but also decrease Ang II levels in patients to attenuate the effects of disease progression.

294

295 **Funding**

296 This study was partially funded by the New Energy and Industrial Technology Development Organization
297 (NEDO) (to J.O.) and the Ministry of Health and Welfare of Japan and Public/Private R&D Investment Strategic
298 Expansion Program: PRISM (to J.O.).

299

300 **Data availability**

301 The nucleotide sequence data of EntCP is available with accession number LC739013. The genome data of the
302 *Enterobacter* sp. 200527-13 is available with accession number BSCM01000001-BSCM01000033.

303

304 **Author contribution**

305 MT and JO conceived of and designed the study. INL and TM conducted experiments. INL, MT, and JO analyzed
306 the data. INL, MT, and JO wrote the manuscript. All authors have read and approved the manuscript.

307

308 **Disclosure statement**

309 All authors declare that they have no conflicts of interest.
