1. Introduction and Preliminaries. We denote a two-dimensional deterministic (nondeterministic) one-marker automaton by "2-DM₁" ("2-NM₁"), and a three-way two-dimensional deterministic (nondeterministic) Turing machine by "TR2-DTM" ("TR2-NTM"). In this paper, we show that the necessary and sufficient space for TR2-NTM's to simulate 2-DM₁'s (2-NM₁'s) is $n \log n (n^2)$, and the necessary and sufficient space for TR2-DTM's to simulate 2-DM₁'s (2-NM₁'s) is $2^{O(n \log n)} (2^{O(n^2)})$, where n is the number of columns of rectangular input tapes.

In this paper, the detailed definitions of two-dimensional marker automata and (space-bounded) three-way two-dimensional Turing machines are omitted. If necessary, refer to [1,2].

Definition 1. Let Σ be a finite set of symbols. A *two-dimensional tape* over Σ is a two-dimensional rectangular array of elements of Σ .

The set of all two-dimensional tapes over Σ is denoted by $\Sigma^{(2)}$.

For a tape $x \in \Sigma^{(2)}$, we let $Q_1(x)$ be the number of rows of x and $Q_2(x)$ be the number of columns of x . If $1 \leq i \leq Q_1(x)$ and $1 \leq j \leq Q_2(x)$, we let $x(i, j)$ denote the symbol in x with coordinates (i, j) . Furthermore, we define

$$x[(i, j), (i', j')],$$

when $1 \leq i \leq i' \leq Q_1(x)$ and $1 \leq j \leq j' \leq Q_2(x)$, as the two-dimensional tape z satisfying

the following:

$$(i) \quad \varrho_1(z) = i' - i + 1 \text{ and } \varrho_2(z) = j' - j + 1,$$

$$(ii) \text{ for each } k, r \ [1 \leq k \leq \varrho_1(z), 1 \leq r \leq \varrho_2(z)], \ z(k, r) = x(k+i-1, r+j-1).$$

When a two-dimensional tape x is given to any two-dimensional automaton as an input, x is surrounded by the boundary symbol "#".

Definition 2. Let x be in $\Sigma^{(2)}$ and $\varrho_2(x) = n$. When $\varrho_1(x)$ is divided by n , we call

$$x[((j-1)n+1, 1), (jn, n)]$$

an n -block of x , for each $j (1 \leq j \leq \varrho_1(x)/n)$.

Definition 3. For any two-dimensional automaton M with input alphabet Σ , define

$$T(M) = \{x \in \Sigma^{(2)} \mid M \text{ accepts } x\}.$$

Furthermore, define

$$\mathcal{L}[2\text{-DM}_1] = \{T \mid T = T(M) \text{ for some } 2\text{-DM}_1 M\} \text{ and}$$

$$\mathcal{L}[2\text{-NM}_1] = \{T \mid T = T(M) \text{ for some } 2\text{-NM}_1 M\}.$$

We similarly define $\mathcal{L}[\text{TR2-DTM}(L(m, n))]$ ($\mathcal{L}[\text{TR2-NTM}(L(m, n))]$) as the class of sets accepted by $L(m, n)$ space-bounded TR2-DTMs (TR2-NTMs).

By using an ordinary technique, We can easily show that the following theorem holds.

Theorem 1. For any function $L(m, n) \geq \log n$,

$$\mathcal{L}[\text{TR2-NTM}(L(m, n))] \subseteq \mathcal{L}[\text{TR2-DTM}(2^{O(L(m, n))})].$$

2. Sufficient Space.

In this section, we investigate the sufficient space for three-way Turing machines to simulate 1-marker automata.

We first show that $n \log n$ space is sufficient for TR2-NTM's to simulate 2-DM₁'s.

Theorem 2. $\mathcal{L}[2\text{-DM}_1] \subseteq \mathcal{L}[\text{TR2-NTM}(n \log n)]$.

Proof. Suppose that a 2-DM₁ M is given. Let the set of states of M be S. We partition S into two disjoint subsets S⁺ and S⁻ which corresponds to the sets of states when M is holding and not holding the marker in the finite control, respectively.¹ We assume that the initial state q₀ and the unique accepting state q_a of M are both in S⁺. In order to make our proof clear, we also assume that M begins to move with its input head on the rightmost bottom boundary symbol # of an input tape and, when M accepts an input, it enters the accepting state at the rightmost bottom boundary symbol.

Suppose that an input tape x with $Q_1(x)=m$ and $Q_2(x)=n$ is given to M. For M and x, we define three types of mappings $f^{+-i}: S^- \times \{0, 1, \dots, n+1\} \rightarrow S^- \times \{0, 1, \dots, n+1\} \cup \{\emptyset\}$, $f^{+i}: S^+ \times \{0, 1, \dots, n+1\} \rightarrow S^+ \times \{0, 1, \dots, n+1\} \cup \{\emptyset\}$, and $f^{+-i}: S^- \times \{0, 1, \dots, n+1\} \rightarrow S^- \times \{0, 1, \dots, n+1\} \cup \{\emptyset\}$ ($i=0, 1, \dots, m+1$) as follows.

$f^{+-i}(q^-, j) = \begin{cases} (q^-, j') \end{cases}$: Suppose that we make M start from the configura-

1. Rigorously, S⁻ does not contain the states in which the input head of M positions on the same cell as where the marker is placed.

Q : Starting from the configuration $(q^-, (i-1, j))$ with no marker on the input tape, M never reaches the i -th row of x .

$f^{+}_i(q^+, j) = \left\{ \begin{array}{l} (q^+, j') : \text{Suppose that we make M start from the configuration } (q^+, (i-1, j)). \text{ After that, if M reaches the } i\text{-th row of } x \text{ with its marker held in the finite control in some time (so, when M puts down the marker on the way, it must return to this position again and pick up the marker), the configuration corresponding to the first arrival is } (q^+, (i, j')); \\ Q : \text{Starting from the configuration } (q^+, (i-1, j)) \text{ with no marker on the tape, M never reaches the } i\text{-th row of } x \text{ with its marker held in the finite control.} \end{array} \right.$

$f^{-}_i(q^-, j) = \left\{ \begin{array}{l} (q^-, j') : \text{Suppose that we make M start from the configuration } (q^-, (i+1, j)) \text{ with no marker on the input tape (i.e., we take away the marker from the input tape by force). After that, if M reaches the } i\text{-th row of } x \text{ in some time, the configura-} \end{array} \right.$

tion corresponding to the first arrival is $(q^-, (i, j'))$,

\bar{Q} : Starting from the configuration $(q^-, (i+1, j))$ with no marker on the tape, M never reaches the i -th row of x .

Below, we show that there exists a TR2-NTM($n \log n$) M such that $T(M') = T(M)$. Roughly speaking, while scanning from the top row down to the bottom row of the input, M' guesses and checks f^{+}_{-i} , constructs f^{+}_{-i} and f^{+}_{+i} , and finally at the bottom row of the input, M' decides by using f^{+}_{-m+1} and f^{+}_{+m+1} whether or not M accepts x (see Figure 1). In order to record these mappings for each i , $O(n)$ blocks of $O(\log n)$ size suffice, so totally $O(n \log n)$ cells of the working tape suffice. More precisely, the working tape must be used as a "multi-track" tape. In the following discussion, we omit the detailed construction of the working tape of M' .

First, set f^{+}_{-0} , f^{+}_{+0} to the fixed value \bar{Q} .

For $i=0$ to $m+1$, repeat the following. [f^{+}_{-i} , f^{+}_{+i} are already computed at the $(i-1)$ st row.]

- (0) Go to the i -th row; When $i=0$, assume the boundary symbols on the first row.
- (1) Guess f^{+}_{-i} ; if $i=m+1$, set f^{+}_{-m+1} to the fixed value \bar{Q} .
- (2) [compute f^{+}_{-i+1} from f^{+}_{-i}] When $i \neq m+1$, do the following: Assume that there is no marker on the input tape. For each $(q^-, j) \in S \times \{0, 1, \dots, n+1\}$, start to simulate M from the configuration $(q^-, (i, j))$. While M moves only at the i -th row, behave just as M does. On the way of the simulation, if M would go up to the $(i-1)$ st row at the k -th

column and would enter the internal state p^- , then search the table $f^{+,-}_i$ to know the behavior of M above the i -th row. If the value $f^{+,-}_i(p^-,k)$ is " Q ", write " Q " into the block corresponding to $f^{+,-}_{i+1}(q^-,j)$; If the value $f^{+,-}_i(p^-,k)$ is " (p^-,k') ", restart the simulation of M from the configuration $(p^-, (i,k'))$. While continuing to move in this way, if M would go down to the $(i+1)$ st row, then write the pair of the internal state and column number just after that movement into the block corresponding to $f^{+,-}_{i+1}(q^-,j)$ of the working tape. If M never goes down to the $(i+1)$ st row (including the case when M enters a loop), then write " Q " into the correspondent block.

- (3) [compute $f^{+,-}_{i+1}$ from $f^{+,-}_i, f^{+,-}_{i+1}$, and $f^{+,-}_i$] When $i \neq m+1$, do the following: For each $(q^+,j) \in S^+ \times \{0,1,\dots,n+1\}$, starting from the configuration $(q^+, (i,j))$, simulate M until M goes down to the $(i+1)$ st row with the marker in the finite control. On the way of the simulation, if M would go up to the $(i-1)$ st row with the marker held, then search the table $f^{+,-}_i$ to know the behavior of M above the i -th row. If this value of $f^{+,-}_i$ is " Q ", write " Q " into the block corresponding to $f^{+,-}_{i+1}(q^+,j)$; otherwise, restart the simulation of M from the configuration on the i -th row determined by the table value. If M puts the marker down on the i -th row of the input tape, then record the column number of this position in some track of the working tape and start the simulation of M which has no marker in the finite control. After that, If M would go down to the $(i+1)$ st row or would go up to the $(i-1)$ st row, then search the respective table $f^{+,-}_i$ or $f^{+,-}_i$ to find the configuration in which M return to the i -th row again. (If M never returns to the i -th row, write " Q " into the block corresponding to $f^{+,-}_{i+1}(q^+,j)$). From this configuration, restart the simulation of M . After that, if M returns to

the position where M put down the marker previously and picks it up, then continue the simulation of M ; otherwise write " \emptyset " into the block corresponding to (q^+, j) . At some point of the simulation, If M goes down to the $(i+1)$ st row with the marker held in the finite control, write the pair of the internal state which M would enter just after that time and the row number of this head position into the block corresponding to $f^{+}_{i+1}(q^+, j)$. If M never goes down to the $(i+1)$ st row, then write " \emptyset " into the correspondent block.

- (4) [check f^{+}_{i-1} from f^{+}_{i}] When $i \neq 0$, do the following: In order to check that the table f^{+}_{i-1} guessed on the previous row is consistent with the table f^{+}_{i} (guessed at the present row), first newly compute a mapping \underline{f}^{+}_{i-1} , which is uniquely determined from f^{+}_{i} and the content of the i -th row of the input. After this computation, check that \underline{f}^{+}_{i-1} is identical to the mapping f^{+}_{i-1} guessed at the previous row. If the equality holds, then continue the process; otherwise, reject and halt.

After the above procedure, on the $(m+1)$ st row, M' begins to simulate M from the initial configuration $(q^+_0, (m+1, n+1))$ to decide whether or not M accepts the input after all. When M goes up to the m -th row with or without the marker, we can know how M returns again to the $(m+1)$ st row, from f^{+}_{m+1} or \underline{f}^{+}_{m+1} , respectively. If M never returns to the $(m+1)$ st row again, then M' rejects and halts. If M returns to the $(m+1)$ th row, then M' continues the simulation. M' accepts the input x only if M' finds that M enters the accepting configuration $(q^+_a, (m+1, n+1))$.

It will be obvious that $T(M) = T(M')$.

From Theorem 1 and Theorem 2, we get the following. ■

Corollary 1. $\mathcal{L}[2\text{-DM}_1] \subseteq \mathcal{L}[\text{TR2-DTM}(2^{O(n \log n)})]$.

We next investigate sufficient space for TR2-NIM's to simulate 2-NM₁. By using the same idea as in the proof of Theorem 2, we can show that the following theorem holds.

Theorem 3. $\mathcal{L}[2\text{-NM}_1] \subseteq \mathcal{L}[\text{TR2-NIM}(n^2)]$.

From Theorem 1 and Theorem 3, we get the following.

Corollary 2. $\mathcal{L}[2\text{-NM}_1] \subseteq \mathcal{L}[\text{TR2-DTM}(2^{O(n^2)})]$.

3. Necessary space.

In this section, we show that the algorithms described in the previous section are optimal in some sense. That is, those spaces are required for three-way Turing machines when the spaces depend only on one variable n (i.e., the number of columns of the input tapes).

Lemma 1. Let $T_1 = \{x \in \{0,1\}^{(2)} \mid \exists n \geq 1 [Q_2(x) = n \ \& \ (\text{each row of } x \text{ contains exactly one "1"}) \ \& \ \exists k \geq 2 [(x \text{ has } k \text{ } n\text{-blocks}) \ \& \ (\text{the last } n\text{-block is equal to some other } n\text{-block})]] \}$. Then,

(1) $T_1 \in \mathcal{L}[2\text{-DM}_1]$ and

(2) $T_1 \notin \mathcal{L}[\text{TR2-DTM}(2^{L(n)})]$ (so, $T_1 \notin \mathcal{L}[\text{TR2-NIM}(L(n))]$) for any $L: \mathbb{N} \rightarrow \mathbb{R}$ such that $\lim_{n \rightarrow \infty} [L(n)/n \log n] = 0$.

Proof. (1): We can easily construct a 2-DM₁ M accepting T_1 as shown in Fig.2.

(2): The proof of Part (2) is lengthy, so omitted here. ■

Lemma 2. Let $T_2 = \{x \in \{0,1\}^{(2)} \mid \exists n \geq 1 [Q_2(x) = n \ \& \ \exists k \geq 2 [(x \text{ has } k \text{ } n\text{-blocks}) \ \& \ (\text{the last } n\text{-block is equal to some other } n\text{-block})]]]\}$. Then,

(1) $T_2 \in \mathcal{L}[2\text{-NM}_1]$,

(2) $T_2 \notin \mathcal{L}[\text{TR2-DTM}(2^{L(n)})]$ (so, $T_2 \notin \mathcal{L}[\text{TR2-NTM}(L(n))]$) for any $L: \mathbb{N} \rightarrow \mathbb{R}$ such that $\lim_{n \rightarrow \infty} [L(n)/n^2] = 0$.

Proof. It is shown in [3] that Part (1) holds. From the same reason as in the proof of Lemma 1(2), we omit the proof of Part (2). ■

From Lemma 1 and Lemma 2, we can conclude as follows.

Theorem 4. To simulate 2-DM₁'s, (1) TR2-NTM's require $\Omega(n \log n)$ space and (2) TR2-DTM's require $2^{\Omega(n \log n)}$ space in general.

Theorem 5. To simulate 2-NM₁'s, (1) TR2-NTM's require $\Omega(n^2)$ space and (2) TR2-DTM's require $2^{\Omega(n^2)}$ space in general.
