MONADIC RECURSION SCHEMES WITH TWO EXITS

YUTAKA KANAYAMA

UNIVERSITY OF TSUKUBA
INSTITUTE OF INFORMATION SCIENCE
SAKURA, IBARAKI 305 JAPAN

ABSTRACT

This paper presents a new language whose describing ability is in a sense equal to monadic recursion schemes, and a formal axiom system which derives strong equivalence among monadic recursion schemes. The main feature of the K-schemes is that each scheme has one entry and two exits. Basic theorems and a few more complex examples are presented.
1. Introduction

Monadic recursion schemes have been extensively studied as models of computer programs [1][2][3][4][5]. In the class of Ianov schemes, which is a restricted class of monadic recursion schemes, the equivalence problem is solvable [6]. Friedman and others have demonstrated that the strong equivalence problem for monadic recursion schemes is decidable if and only if the equivalence problem for languages accepted by deterministic pushdown automata is decidable [3][5].

The main purposes of this papers are to propose a new method for describing monadic program schemes, and to propose a powerful axiom system, the K-system, by which the equivalence among schemes can be deduced. A similar system, μ-calculus, has already been presented by deBakker [2]. Since almost all of its axioms are proven from more elementary axioms, the K-system may be said to be a refined variation of μ-calculus.

The flavor of the K-system will be given through simple examples. Consider the following programs:

A: \[ \text{t:=f(t); while } p(t) \text{ do } t:=f(t) \]

B: \[ \text{repeat } t:=f(t) \text{ until } \neg p(t) \]

Their equivalent flowcharts are shown in Figure 1 and 2 respectively. Here t is the only program variable. The equivalence of the two algorithms could be shown by using a formal method having the power of mathematical induction. In the K-system, these algorithms are expressed as \( f_{μx}(pfx) \) and \( μx(fpfx) \) respectively and the equivalence is proven in Example 4.2.
Let us define two monadic recursion schemes \( F \) and \( G \) as follows:

\[
F(t) = \begin{cases} \text{if } p(t) \text{ then } g(F(f(t))) \text{ else } g(h(t)) \\ G(t) = g(G_1(t)) \\ G_1(t) = \begin{cases} \text{if } p(t) \text{ then } g(G_1(f(t))) \text{ else } h(t) \end{cases} \end{cases}
\]

They are translated into K-language as \( \mu x(\text{pfx} x g h g) \) and \( (\mu x(\text{pfx} x g h)) g \) respectively and the equivalence is proved also in Example 4.2.

The principal features of K-language are as follows:

(1) Every scheme can have one entry and two exits. (Thus we can say that one-exitness is not a necessary condition for structured programming.)

(2) The dual operators \((-\) and \(\cdot\) are used instead of \(<;>\) and \(<\text{if then else}>\).

(3) The negation operator \((-\) is introduced.

(4) The recursive or naming operator \(\mu\) is used [2].

(5) Each scheme is expressed by a single expression instead of a system of simultaneous equations.

The axiom system to be presented is, in a sense, a mixture of Boolean algebra and the system for regular expressions [7]. Although the completeness of the system is still unknown, it seems at least to be a powerful tool for the investigation of monadic recursion schemes and control flow of computer programs, because we have been successful in proving many basic equalities and some sophisticated examples.
2. Syntax

We are interested in monadic recursion schemes in a special form. That language is called K-language. In this section, the syntax of K-language and some syntax-related properties are defined. The property of a scheme having or not having two exits is an example of a syntactical property. Those properties about expressions are important in the deductive procedure presented in Section 3.

2.1 K-schemes

In this system, we have

1. The set of function symbols \( A = \{ 1, 0, f_1, f_2, \ldots \} \).
2. The set of predicate symbols \( P = \{ p_1, p_2, \ldots \} \).
3. The set of variables \( V = \{ x_1, x_2, \ldots \} \).

Sometimes \( f, g, p, q, x \) or \( y \) are used instead of \( f_1, f_2, p_1, p_2, x_1 \) or \( x_2 \) respectively. The set \( B = A \cup P \) is called the set of basic symbols.

Each K-scheme, or simply scheme, is constructed by basic symbols, variables, parentheses and operators \( ., +, - \) and \( \mu \).

Definition 3.1

Schemes are defined as follows:

1. If \( s \in B \cup V \), then \( s \) is a scheme. That is, every basic symbol or variable itself is a scheme.
2. If \( F \) and \( G \) are schemes and \( x \) is a variable, then \( (F \cdot G) \), \( (F+G) \), \( (-F) \) and \( (\mu x F) \) are schemes.

Example 2.1 The followings are schemes.
\[
a, (p \cdot q), (\mu x ((p \cdot f) \cdot x \cdot g)), (-((-p) + (-q))).
\]
We write \( F = G \) if \( F \) and \( G \) are identical strings. If \( G \) is a substring of a scheme \( F \) and \( F \) is a scheme, then we write \( G \preceq F \) and \( G \) is called a subscheme of \( F \). For any scheme \( F \), \( F \preceq F \).

The number of occurrences of operators \( \cdot \), \( + \), \( - \) and \( \mu \) in a scheme \( F \) is called the height of \( F \) and denoted by \( \text{ht}(F) \).

In a scheme \( (\mu x F) \), \( F \) is called a scope of \( \mu x \). An occurrence of a variable \( x \) is said to be bound if it occurs immediately after \( \mu \) or in a scope of \( \mu x \). If an occurrence of a variable is not bound, then it is said to be free. A program without free occurrences of variables is said to be closed. A scheme \( G \) is said to be free for \( x \) in \( F \), if no free occurrences of \( x \) in \( F \) lie within the scope of any \( \mu y \), where a free \( y \) occurs in \( G \).

**Example 2.2**

We may omit parentheses and operators by using the following rules:

1. The operators are put in order of strength as follows: \(+\), \(-\), \(\cdot\), \(\mu\).
2. The dots may be omitted.
3. The outermost parentheses may be omitted.
4. \((-F)\) may be written as \(\overline{F}\).

Hereafter, \(\ast\) stands for the operator \(\cdot\) or \(+\).

**Example 2.3** Schemes shown in Example 2.1 are represented in an abbreviated form as follows:

\[ a, pq, \mu x((pf)x + g), \overline{p + q}. \]

\(F[H/G]\) denotes a scheme obtained from \(F\) by replacing an occurrence of \(G\) by \(H\).

\(F[G/x]_F\) denotes a scheme obtained from \(F\) by replacing all free occurrences of \(x\) by \(G\).
Example 2.4

If $F \equiv G \equiv pf x + g$, then $F[G/x]_F \equiv pf(pfx + g) + g$. If $H \equiv pf x + \mu x(qhx)$, then $H[G/x]_F \equiv pf(pfx + g) + \mu x(qhx)$.

2.2 Syntactical Properties

Several syntactical properties of schemes, such as the concept of entry, exit, boolean-ness and regularity, will be defined in this section.

Let $G$ be a subscheme of $F$. If the relation $G \leq_{en} F$ is derived by using the following rules, $G$ is said to be an entry of $F^+$:

1. $F \leq_{en} F$ for every $F$.
2. If $G \leq_{en} F$, then $G \leq_{en} (F \ast H)$ and $G \leq_{en} F$ for every $F$, $G$ and $H$.

Example 2.5

$F \leq_{en} F(GH)$, $F \leq_{en} (FG)H$, $F \leq_{en} FG$ and $F \leq_{en} FG + H$.

See Propositions 4.1 and 4.2.

A skeleton of a scheme $F$ is an approximation of $F$ that does not contain $\mu$ operators. This concept is used in testing whether a scheme has a dot-exit or a plus-exit. A skeleton $sk(F)$ of a scheme $F$ is recursively defined as follows:

1. $sk(a) = a$, if $a \in B \cup V$.
2. $sk(F \ast G) = sk(F) \ast sk(G)$.
3. $sk(F) = \overline{sk(F)}$.
4. $sk(\mu x F) = sk(F)[sk(F)[\emptyset/x]_F/x]_F$.

Example 2.6

$sk(pf + g) = pf + g$
$sk(px) = px$
$sk(\mu x(px)) = p(p0)$
$sk(\mu x(p\bar{x})) = pp\bar{0}$

† In the flowchart representation of schemes shown in Figure 3, an entry of $F$ is a box or a set of boxes in $F$ which is located at the upper left corner of $F$. 
The concept of the dot exit and the plus exit of a scheme is clear if we express it in flowchart representation (See Figure 3). Strictly speaking, however, the property about the exits of schemes can be defined syntactically. If $ef'^*(F)$ or $ef'^+(F)$ is derived by using the following rules, the scheme $F$ is said to be dot-exit free or plus-exit free respectively:

1. $ef'^+(f)$, if $f \in A$.
   $ef'^*(\emptyset)$.
2. $ef'^*(F \cdot G) = ef'^*(G)$.
3. $ef'^*(F \cdot G) = ef'^*(F) \land ef'^*(G)$. (\textit{\neg}\neg and \textit{\neg}.)
4. $ef'^*(\textbf{F}) = ef'^*(F)$.
5. $ef'^*(\textbf{ux}F) = ef'^*(sk(\textbf{ux}F))$.

Every scheme is considered to have at most two exits, the dot exit and the plus exit (see Figure 3). For example, the scheme $pf$ has both exits. Some schemes have, however, only one exit or no exits at all. For example, $pf\cdot g$ does not have the plus exit.

Example 2.7

$ef'^+(pf\cdot g) = ef'^+(g) = \text{true}$.

$ef'^*(p\emptyset) = ef'^*(\emptyset) = \text{true}$.

$ef'^*(px) = ef'^*(x) = \text{false}$.

$ef'^*(\text{ux}(px)) = ef'^*(sk(\text{ux}(px))) = ef'^*(px)[(px)[\emptyset/x]_f/x]_f$ = $ef'^*(p(\emptyset)) = ef'^*(p\emptyset) = ef'^*(\emptyset) = \text{true}$.

$ef'^*(\text{ux}(p\overline{x})) = ef'^*(sk(\text{ux}(p\overline{x}))) = ef'^*(p\overline{x})[(p\overline{x})[\emptyset/x]_f/x]_f$ = $ef'^*(pp\overline{u}) = ef'^*(p\overline{u}) = ef'^+(p\overline{u}) = ef'^+(p)\land ef'^+(\overline{u}) = \text{false} \land ef'^*(\emptyset) = \text{false}$.

We will define the "boolean" property of a scheme. If $bl'^*(F)$ is derived by using the following rules, $F$ is said to be $*$-boolean$^+$:

$^+$ If $bl'^*(F)$, then there exist no function symbols on any path from entry of $F$ to the $*$-exit.
(1) $b_{1}^{-}(s)$, if $s \in P \cup \{0, 1\}$.

$\forall (s, i) \in B (= A \cup P)$.

(2) $b_{1}^{-}(F \ast G) = b_{1}^{-}(F) \wedge b_{1}^{-}(G)$.

(3) $b_{1}^{-}(F \ast \overline{G}) = b_{1}^{-}(F) \wedge b_{1}^{-}(F) \wedge b_{1}^{-}(G)$.

(4) $b_{1}^{-}(\overline{F}) = b_{1}^{-}(\overline{F})$.

(5) If $ef^{+}(F)$, then $b_{1}^{-}(F)$.

Example 2.8

$b_{1}^{-}(p), b_{1}^{+}(p), b_{1}^{+}(pf), b_{1}^{-}(\overline{p}), b_{1}^{-}(pq)$ and $b_{1}^{+}(pq)$.

Suppose $G$ is a subscheme of a scheme $F$. If $G \leq b_{1}^{-}F$ is derived by using the following rules, $G$ is said to be boolean in $F$:

(1) $F \leq b_{1}^{-}F$.

(2) If $b_{1}^{-}(F_1)$ and $G \leq b_{1}^{-}F_2$, then $G \leq b_{1}^{-}(F_1 \ast F_2)$.

(3) If $G \leq b_{1}^{-}F_1$, then $G \leq b_{1}^{-}(F_1 \ast F_2)$ and $G \leq b_{1}^{-}F_1$.

Example 2.9

$p \leq b_{1}^{-}(pq), p \leq b_{1}^{-}(qp)$ and $F \leq b_{1}^{-}(pq + F)$ and $H \leq b_{1}^{-}(pF + qG + H)$

if $ef^{+}(F)$ and $ef^{+}(G)$.

$F[H/G]_{b_{1}}$ denotes a scheme which is obtained from $F$ by replacing (possibly null) occurrences of $G$ by $H$ such that $G \leq b_{1}^{-}F$.

Example 2.10

Take $F \equiv pq, G \equiv pp$ and $H \equiv qp + fp$. Then $F[1/p]_{b_{1}} \equiv 1q$,

$F[1/q]_{b_{1}} \equiv p1, G[1/p]_{b_{1}} \equiv 11, G[1/q]_{b_{1}} \equiv pp$ and $H[1/p]_{b_{1}} = q1 + fp$.

Consider schemes $pq$ and $pf + g$ and their flow chart equivalents. In the first, the value of the program variable $t$ does not change during execution. On the other hand, assignment operations to $t$, $t := f(t)$ or $t := g(t)$, occur during the execution of the second. We
will syntactically define the property of an exit of a scheme as follows:

If \( rg'(F) (rg^+(F)) \) is derived by using the following rules, \( F \) is said to be dot-regular (plus-regular):

(1) \( rg'(f), \text{ if } f \in A - \{1\}. \)
    \( rg^+(f), \text{ if } f \in A. \)

(2) \( rg(F \cdot G) = rg(F) \lor rg(G). \)

(3) \( rg(F \oplus G) = rg(F) \land (rg'(F) \lor rg'(G)). \)

(4) \( \neg rg(F) = \neg rg(F) \)

(5) \( rg'(F) \text{ if } ef'(F) \)

Example 2.11

\( rg'(pf), rg'(fp), rg^+(F), rg'(pf+g) \text{ and } rg'((p+q)(pf+g)) \).

See Proposition 4.3.

Assume that \( G \) is a subscheme of a scheme \( F \). If \( G \leq_{rg} F \) is derived by using the following rules, then \( G \) is said to be regular in \( F^+ \):

(1) If \( \neg rg(F_1) \text{ and } G \leq_{rg} F_2, \text{ then } G \leq_{rg} (F_1 \cdot F_2). \)

(2) If \( G \leq_{rg} F_1, \text{ then } G \leq_{rg} (F_1 \cdot F_2), G \leq_{rg} (F_2 \cdot F_1) \text{ and } G \leq_{rg} \overline{F}_1. \)

Example 2.12

\( F \leq_{rg} (fpF), H \leq_{rg} (fphF + G) \text{ and } F \leq_{rg} (pfFg + HG). \)

See Example 4.2.

\( \dagger \) If \( G \leq_{rg} F \), then there exists at least one function symbol on any path from the entry of \( F \) to the entry of \( G \), or there exist no paths from the entry of \( F \) to the entry of \( G \).
The Axiom System

The purpose of this section is to present the axiom system $K$ for deducing equivalence among $K$-schemes. This system resembles the system of regular expressions by Salomaa [7] and the one of Boolean Algebra. Relations between program schemes and regular expressions have been discussed in many papers [8][9].

We are interested in an equation $F = G$ between two schemes $F$ and $G$. The meaning of the equation is described in Section 5. The purpose of $K$ is to derive "valid equalities" among schemes. The next section demonstrates several equations whose two sides are quite different in form. The $K$ system consists of eight axioms $A_1 \sim A_8$ and four inference rules $R_1 \sim R_4$. If $F$, $G$, $H$ and $J$ are any schemes, $x$ is any variable, and $p$ is any predicate symbol, then the following $(A_1) \sim (A_8)$ are axioms and $(R_1) \sim (R_4)$ are rules of inference of $K$. Here $H[G/F]$ denotes a scheme which is obtained from $H$ by replacing an occurrence of $F$ by $G$.

$A_1 \quad \bar{\bar{1}} = 1.$

$A_2 \quad \bar{1}F = F.$

$A_3 \quad 1 + F = 1.$

$A_4 \quad \bar{1} + F = F.$

$A_5 \quad \bar{F} = \bar{1}.$

$A_6 \quad F = 0$, if $\text{ef}^{-}(F)$ and $\text{ef}^{+}(F)$.

$A_7 \quad \mu xF = P[\mu xF/x]_{F}$, if $F$ is free for $x$ in $F$.

$A_8 \quad \mu xF = \mu x(F[0/x]_{b_1})$

$R_2$(Entry) Assume that $H \leq_{en} F$ and $H \leq_{en} G$. Then $F = G$ is a direct consequence of $F[1/H] = G[1/H]$ and $F[\bar{1}/H] = G[\bar{1}/H]$.

$R_2^{+}$(Entry) Assume that $H \leq_{en} F$, $H \leq_{en} G$ and $\text{ef}^{+}(H)$. Then $F = G$ is a direct consequence of $F[1/H] = G[1/H]$. 
R2' (Entry) Assume that $H \leq_{en} F$, $H \leq_{en} G$ and $ef'(H)$. Then $F = G$

is a direct consequence of $F[I/H] = G[I/H]$.

R3 (Boolean) $F = G$ is a direct consequence

of $F[l/p]_{b1} = G[l/p]_{b1}$ and $F[I/p]_{b1} = G[I/p]_{b1}$.

R4 (Solution of equations) Assume that $F$ is free for $x$ in $G[x/F]_{rg}$

and $x$ is not a free variable in $G$. Then $F = \mu x G[x/F]_{rg}$ is

da direct consequence of $F = G$.

An equation $E$ is said to be a consequence of a set of equations $E$ iff there is a sequence $E_1, \ldots, E_n$ of equations such that $E = E_n$ and, for each $i$, either $E_i$ is an axiom, $E_i \in E$, or $E_i$ is a direct consequence by some rule of inference of some of the preceding schemes in the sequence. We write $\vdash E$ as an abbreviation for "$E$ is a consequence of $E$". If $E$ is the empty set, we write $\vdash E$, and $E$ is called a theorem.

Example 3.1 $F_1 = F_2 \vdash F_2 = F_1$, because $F_2 = F_1$ is a direct consequence

of $F_1 = F_2$ if we take $F = F_1$, $G = F_2$ and $H = F_1$ in $Rl$. 
4. Basic theorems and examples

Some important results and interesting examples derived from the K-system are presented in this section.

The substitution rule R1 and the results in the following lemma are used below without being explicitly referred to.

Lemma 4.1 If ⊢ F = G, then ⊢ G = F. If ⊢ F = G and ⊢ G = H, then

 ⊢ F = H. ⊢ F = F. If ⊢ F = G and ⊢ H = J, then ⊢ FH = GJ, ⊢ F + H = G + J,

 ⊢ F = G and ⊢ μx F = μx G.

The proof of Lemma 1 is straightforward, by R1 and A2. The next Lemma permits renaming of bound variables as in predicate calculus.

Lemma 4.2 If F is free for x in F, F is free for y in F, all free occurrences of x are regular in F and there exists no free occurrences of y in F, then

 ⊢ μx F = μy F[y/x]_rg.

In the following, the dual results are shown in pairs.

Proposition 4.1

(1) ⊢ (FG)H = F(GH), ⊢ (F+G)+H = F+(G+H)
(2) ⊢ F+G = F+G, ⊢ F+G = F+G (See Figure 4)
(3) ⊢ F 1 = F, ⊢ F + 1 = F
(4) ⊢ F + 1 = F + 1, ⊢ F 1 = F 1

The proof of Proposition 4.1 is by R2 and A1 ~ A5. Part (2) is similar to De Morgan's theorem in Boolean algebra.

Proposition 4.2

(1) ⊢ F + G = F, if ef^+(F). ⊢ FG = F if ef^+(F).
(2) ⊢ (F+G)H = FH+GH if ef^+(H). ⊢ FG+H = (F+H)(G+H) if ef^+(H).
(3) ⊢ FG+H = F(G+H)+H if ef^+(H). ⊢ (F+G)H = (F+GH)H if ef^+(H).

(See Figure 5)
(4) \( \vdash (FG+H) = \overline{F}H+G \) if \( ef^+(G) \) and \( ef^+(H) \).
\( \vdash (F+G)H = (\overline{F}+H)G \) if \( ef^+(G) \) and \( ef^+(H) \).
(5) \( \vdash \overline{F}+G = FG \) if \( ef^+(F) \).
(6) \( \vdash FG+H = F(G+H) \) if \( ef^+(F) \).
\( \vdash (F+G)H = F+GH \) if \( ef^+(F) \).

The proof of Proposition 4.2 is by R2\(^+\), R1\(^-\) and R2.

**Proposition 4.3**

1. \( \vdash pp = p, \ \vdash p+p = p. \)
2. \( \vdash p\overline{p} = \overline{1}, \ \vdash p+p = 1. \)
3. \( \vdash p+\overline{1} = \overline{1}, \ \vdash p\overline{1} = \overline{1}. \)
4. \( \vdash pq = qp, \ \vdash p+q = q+p. \)
5. \( \vdash pF+F = F, \) if \( ef^+(F) \).
\( \vdash (p+F)F = F \) if \( ef^+(F) \).
6. \( \vdash p(F+G) = p(pF+G), \ \vdash p+FG = p+(p+F)G. \) (See Figure 6)
7. \( \vdash pF+pG = pF \) if \( ef^+(F) \), \( \vdash (p+F)(p+G) = p+F \) if \( ef^+(F). \)
8. \( \vdash pqF+pg+qH = pqF+qH+pg, \) if \( ef^+(F), \) \( ef^+(G) \) and \( ef^+(H). \)
\( \vdash (p+q+F)(p+G)(q+H) = (p+q+F)(q+H)(p+G), \) if \( ef^+(F), \) \( ef^+(G) \) and \( ef^+(H). \)
9. \( \vdash p(qF_1+F_2)+qF_3+F_4 = q(pF_1+F_3)+pF_2+F_4 \) if \( ef^+(F_1), \) \( ef^+(F_2), \)
\( ef^+(F_3) \) and \( ef^+(F_4). \)
\( \vdash (p+(q+F_1)F_2)(q+F_3)F_4 = (q+(p+F_1)F_3)(p+F_2)F_4 \) if \( ef^+(F_1), \)
\( ef^+(F_2), \) \( ef^+(F_3) \) and \( ef^+(F_4). \)

Proof. (1) The proof of the first equation is:

(a) \( 11 = 1 \) \quad A2.
(b) \( \overline{11} = \overline{1} \) \quad A5.
(c) \( pp = p \) \quad (a), (b) and R3.

The remaining proofs are omitted.
Proposition 4.4 Assume that \( \text{ef}^+(F) \) and \( \text{ef}^+(G) \). Then \( \text{pq} = \overline{\overline{I}} \) 
\[ \vdash \text{pF} + \text{qG} = \text{qG} + \text{pF}. \]

Proof. Assume that \( H \) is an arbitrary scheme such that \( \text{ef}^+(H) \).

(1) \( \text{pqH} + \text{pF} + \text{qG} = \text{pqH} + \text{qG} + \text{pF} \) Proposition 4.3(8).

(2) \( \text{pq} = \overline{\overline{I}} \) Hypothesis.

(3) \( \overline{\overline{I}} \text{H} + \text{pF} + \text{qG} = \overline{\overline{I}} \text{H} + \text{qG} + \text{pF} \) (1), (2), Lemma 4.1.

(4) \( \text{pF} + \text{qG} = \text{qG} + \text{pF} \) (3), A5, A4.

Q.E.D.

Hereafter, the set of theorems \( \vdash F_1 = F_2, F_2 = F_3, \ldots, \vdash F_{n-1} = F_n \) are denoted by \( F_1 = F_2 = \cdots = F_n \).

Example 4.1

(1) If \( F = \mu x (pfx + g) \), then 
\[ \vdash F = pF + g \]
\[ = pf(pF + g) + g \]
\[ = pf(pf(pF + g) + g) + g \]
\[ = \ldots \]

(2) If \( G = \mu x (pf(x + h)) \), then 
\[ \vdash G = pF \text{Gf} + h \]
\[ = pf(pfGg + h) + h \]
\[ = pf(pf(pfGg + h) + h) + h \]
\[ = \ldots \]

(3) \( \vdash H = \mu x (pfx + g) \)
\[ = pfHH + g \]
\[ = pf(pfHH + g)(pfHH + g) + g \]
\[ = \ldots \]

(4) \( \vdash J = \mu x (pf\overline{x} + g) \)
\[ = pf\overline{J} + g \]
\[ = pf(pf\overline{J} + g) + g \]
\[ = pf(p + \overline{I} + J) \overline{g} + g \]
\[ = \ldots \]
Example 4.2 Several pairs of equivalent schemes whose recursive structures are not the same are shown here. They are derived by using R4.

(1) \( \vdash f \mu x(fpx) = \mu x(fpx) \) This is because \( F \equiv f \mu x(fpx) = f(f \mu x(fpx)) = fp(f \mu x(fpx)) = fpF \); therefore \( \vdash F = \mu x(fpx) \) by R4.

(2) \( \vdash f \mu x(pfxF+G) = \mu x(fpxF+G) \), where \( F, G \) are arbitrary schemes. This is because, \( \vdash H \equiv f \mu x(pfxF+G) = f(pf \mu x(pfxF+G)F+G) \)

\( = fpf \mu x(pfxF+G)F+G \equiv fpHF + G \); therefore \( \vdash H = \mu x(fpxF+G) \).

(3) \( \vdash \mu x(pfxg) + h = \mu x(pf(pfx+g)+h) \).

Take \( F = \mu x(pfx)g+h \). Then \( \vdash F = pf \mu x(pfx)g+h = pfpf \mu x(pfx)g+h \)

\( = pf(p+pf \mu x(pfx))g+h = pf(pg+pf \mu x(pfx)g)+h \)
\( = pf(pg+pf \mu x(pfx)g)+h = pf(p(f \mu x(pfx)g)+g)+h \)
\( = pf(pf(\mu x(pfx)g)+g)+h = pf(pfF+g)+h \).

Therefore, by R4, \( \vdash F = \mu x(pf(pfx+g)+h) \).

(4) \( \vdash \mu x(pf(xg+h)g) = (\mu x(pf(xg+h))g) \). The idea of this equivalence is based on the example by Korenjack and Hopcroft [10]. (See Figure 7) Take \( F = (\mu x(pf(xg+h))g) \). Then \( \vdash F = (pf \mu x(pf(xg+h))g+h)g \)

\( = pf \mu x(pfxg+h)gg+h = pfFg+hg \). Hence \( \vdash F = \mu x(pf(xg+h)g) \) by R4.

We will show a final example taken from Dijkstra [11].

Example 4.3

Consider the following two programs \( P_1 \) and \( P_2 \), both of which evaluate the greatest common divisor of two natural numbers.

\[ P_1: \text{while } a \neq b \text{ do if } a > b \text{ then } a := a-b \text{ else } b := b-a \]

\[ P_2: \text{while } a \neq b \text{ do begin while } a > b \text{ do } a := a-b \]

\[ \text{while } b > a \text{ do } b := b-a \text{ end} \]

They are rewritten as

\[ P'_a: \text{while } p \lor q \text{ do if } p \text{ then } f \text{ else } g \]

\[ P'_b: \text{while } p \lor q \text{ do begin while } p \text{ do } f; \text{ while } q \text{ do } g \text{ end} \]

where \( p \land q = \text{false} \).
These programs are translated into K-schemes as follows:

\[ F \equiv \mu x((p+q)(pf+g)x+1) \]
\[ G \equiv \mu x((p+q)\mu x(pf+1)ux(qgx+1)x+1) \]

We want to show that \( pq = I \vdash F = G \). Let \( H \equiv \mu x(pf+qgx+1). \)(See Figure 8)

First we demonstrate that \( pq = I \vdash F = H \), and later that \( pq = I \vdash G = H \).

(a) Proof that \( pq = I \vdash F = H \).

\[ I \vdash F \equiv \mu x((p+q)(pf+g)x+1) = (p+q)(pf+g)F + 1 = (p(pf+g)+q(pf+g))F+1 = (pf+qf+g)F+1 = pfF+qF+1. \]

Therefore, \( I \vdash F = \mu x(pf+qgx+1) \equiv H \).

(b) Proof that \( pq = I \vdash G = H \).

\[ I \vdash G \equiv \mu x((p+q)\mu x(pf+1)ux(qgx+1)x+1) = (p+q)\mu x(pf+1)ux(qgx+1)G+1 = (pfux(pf+1)+qux(pf+1))ux(qgx+1)G+1 = (p(fux(pf+1)+1)+q(qfux(pf+1)+1))ux(qgx+1)G+1 = (pfux(pf+1)+1)+q(qfux(pf+1)+1))ux(qgx+1)G+1 = (pfux(pf+1)+q(\mu x(pf+1)+1))ux(qgx+1)G+1 = (pfux(pf+1)+q)ux(qgx+1)G+1 = pfux(pf+1)ux(qgx+1)G+qux(qgx+1)G+1 = pfG+q(qux(qgx+1)+1)G+1 = pfG+qG+1, \]

where \( G \equiv \mu x(pf+1)ux(qgx+1)G \) and \( G \equiv \mu x(qgx+1)G \). Therefore,

\[ I \vdash G_1 \equiv \mu x(pf+1)ux(qgx+1)G = (pfux(pf+1)+1)ux(qgx+1)G = pfux(pf+1)ux(qgx+1)G+1 = pfG_1+q(qux(qgx+1)+1)G = pfG_1+qG_2+1 = pfG_1+qG_2+1 = pfG_1+qG_2+1 = G \]

\[ I \vdash G_2 \equiv \mu x(qgx+1)G = qux(qgx+1)+1)G = qux(qgx+1)G+G = qG_2+pfG_1+qG_2+1 = pfG_1+qG_2+1 = pfG_1+qG_2+1 = G \]

Hence \( I \vdash G_1 = G_2 = G \), and \( I \vdash G = pfG+qG+1 \). Therefore,

\[ I \vdash G = \mu x(pf+qgx+1) = H. \]
5. Semantics

The meaning of a scheme in the K-language is defined in such a way that the class of all interpreted functions from the K-schemes includes the class of all interpreted functions from monadic recursion schemes [4][5].

5.1. Definitions

Let $D$ be any non-empty set. We add a special element $\bot$ to $D$ to obtain the set $D_\bot = D \cup \{\bot\}$. A partial order $\sqsubseteq$ is defined on $D_\bot$ such that $s \sqsubseteq t$ iff $s = \bot$ or $s = t$. If $\phi$ is a total function: $D \rightarrow D$, then it is extended to the function: $D_\bot \rightarrow D_\bot$ such that $\phi(\bot) = \bot$ [12][13].

The least upper bound operation $\sqcup$ is defined as follows:

$t \sqcup \bot = \bot \sqcup t = t \sqcup t = t$ for all $t \in D_\bot$. $s \sqcup t$ is undefined, if $s \neq \bot$, $t \neq \bot$ and $s \neq t$. $\sqcup_{n=0}^\infty t_n = t$ iff $t_n = t$ or $t_n = \bot$ for all $n \geq 0$, and there exists $n$ such that $t_n = t$. The least upper bound $\phi \sqcup \psi$ of functions $\phi$ and $\psi$: $D_\bot \rightarrow D_\bot$ is defined by $(\phi \sqcup \psi)(t) = \phi(t) \sqcup \psi(t)$ for any $t \in D_\bot$. This operation can be extended for the class of enumerable functions $\phi_0$, $\phi_1$, ... .

Let $D^D$ and $2^D$ denote the set of all total functions: $D \rightarrow D$ and the set of all total predicates: $D \rightarrow \{\text{true, false}\}$ respectively. An interpretation $I$ is a quadruple $(D, A, P, V) = (D, A, P, (V^-, V^+))$. where $A$ is a mapping: $A \rightarrow D^D$, $P$ a mapping: $P \rightarrow 2^D$, and $V$ a mapping: $V : D_\bot \times D_\bot$ with a condition that $V^-(x) = \bot$ or $V^+(x) = \bot$ for any $x$.

Assume $I = (X, A, P, V)$. Let us define that $I[(x', x^+) / x]$ stands for an interpretation $I' = (D', A', P', V')$ such that $D' = D$, $A' = A$, $P' = P$ and

$$V'(y) = \begin{cases} V(y), & \text{if } y \neq x \\ (t', t^_), & \text{if } y = x \end{cases}$$
V defines the meaning of free variables. In general, however, the role of V is less important than that of A and F.

The meaning F_I of a scheme F under an interpretation I is a function: D_D × D_D × D_D. That is, for any t ∈ D_D, F_I(t) is a pair (F_I'(t), F_I^+(t)). The function F_I' stands for the dot effects of the all paths of the scheme F between the entry and the exit; the function F_I^+ is defined in the same way with respect the plus exit.

We stipulate that E and ⊥ denote the identity functions and the bottom function on D; i.e., E(t) = t and ⊥(t) = ⊥ for all t ∈ D_D. The composition φ•ψ of functions φ and ψ: D_D → D_D is given by a definition; (φ•ψ)(t) = ψ(φ(t)).

Each scheme is recursively interpreted as follows:

(5.1) Θ_I(t) = (⊥, ⊥) = (⊥, ⊥)(t)
(5.2) Λ_I(t) = (t, ⊥) = (E, ⊥)(t)
(5.3) f_I(t) = (A(f)(t), ⊥) = (A(f), ⊥)(t)
(5.4) p_I(t) = \begin{cases} (t, ⊥), & \text{if } P(p)(t) \\ (⊥, t), & \text{if } Q(p)(t) \end{cases}
(5.5) x_I(t) = (V'(x), V^+(x)) = V(x)
(5.6) (FG)_I(t) = (G_I'(t)•(F_I'(t)), F_I^+(t)∪G_I^+(F_I'(t)))
    = (F_I'•G_I', F_I^+∪(F_I'•G_I^+))(t)
(5.7) (F+G)_I(t) = (F_I'(t)∪G_I'(F_I^+(t)), G_I^+(F_I^+(t)))
    = (F_I'•(F_I^+ G_I'), F_I^+ G_I^+)(t)
(5.8) F_I(t) = (F_I^+(t), F_I'(t)) = (F_I^+, F_I')(t)

(5.9) (μxF)_I(t) = \bigcup_{n=0}^{∞} F_I(x,n(t)),

where \begin{cases} F_I,x,0(t) = (⊥, ⊥) = Θ_I(t) \\ F_I,x,n+1(t) = F_I[F_I,x,n(t)/x],x,n(t); n=0,1,2,... \end{cases}

We may interpret each K-scheme as a flowchart which has at most two exits. That is shown in Figure 3.
Lemma 5.1 If $G$ is free for $x$ in $F$, then $F[I[G/x](t)] = (F[G/x])_I(t)$ for all $F$, $G$, $t$, $x$ and $I$.

We write $F \not\equiv G$ if $F_I = G_I$ for all interpretation $I$.† We want to demonstrate that the axiom system $K$ is consistent. It is helpful if we can fix on one special domain in proving validity of the system. A special class of interpretation, Herbrand interpretations, is introduced here.

The domain $D$ is called the Herbrand universe $H_K$ of $K$ if $D$ consists of the strings,

$$\lambda, f_1, f_2, \ldots, f_1f_1, f_1f_2, \ldots, f_2f_1, \ldots,$$

and $\bot$, where $\lambda$ denotes the empty string. Assume that $\bot t = t \bot = \bot$ for all $t \in H_K$. An interpretation $I$ is called Herbrand if $D = H_K$ and $f_I(t) = tf$ for any $t \in H_K$ and $f \in A$.‡ Hereafter we will treat only Herbrand interpretations, because

Proposition 5.2[14] $F \not\equiv G$ iff $F_I = G_I$ for all Herbrand interpretations $I$.

Example 5.1 Let us show how $pf+g$, $q(pf+g)$ and $\mu x(pf)$ are interpreted under an Herbrand interpretation $I$.

$$
(pf+g)_I(t) = \begin{cases} 
(tf, \bot), & \text{if } P(p)(t) \\
(tg, \bot), & \text{if } \forall P(p)(t)
\end{cases}
$$

$$
(\mu x(pf))_I(t) = \begin{cases} 
(\bot, tf^n), & \text{if } \bigwedge_{m=0}^{n-1} P(p)(tf^m) \land (\forall P(p)(tf^n)) \\
(\bot, \bot), & \text{if } \bigwedge_{m=0}^{\infty} P(p)(tf^m)
\end{cases}
$$

$$
(q(pf+g))_I(t) = \begin{cases} 
(tf, \bot), & \text{if } P(q)(t) \land P(p)(t) \\
(tg, \bot), & \text{if } P(q)(t) \land \forall P(p)(t) \\
(\bot, t), & \text{if } \forall P(q)(t)
\end{cases}
$$

† $F_I = G_I$ means that $F_I(t) = G_I(t)$ for all $t \in DL$.
‡ $F$ and $V$ are, however, not fixed.
5.2 Validity of Axioms

First, we show the validity of the elementary axioms.

Proposition 5.3  For any scheme F,

(1) \( \mathbf{I} \cong \mathbf{I} \)
(2) \( \mathbf{I}F \cong F \)
(3) \( \mathbf{I} + F = F \)
(4) \( \mathbf{I} + F = F \)
(5) \( \mathbf{I}F = \mathbf{I} \)

Second, we show the validity of the axiom about exits.

Lemma 5.4  \( \text{sk}(F[G/x]_F) \cong \text{sk}(F)[\text{sk}(G)/x]_F \) for any F, G and x, if G is free for x in F.

Let us define \( F<x, n> \) for \( n=0, 1, 2, \ldots \) as follows:

(5.10) \( F<x, 0> \equiv 0 \)
(5.11) \( F<x, n+1> \equiv F[F<x, n>/x]_F \), for \( n=0, 1, 2, \ldots \).

Lemma 5.5  If F is free for x in F, then \( F<x, n>_I \cong F_I, x, n \) for all F, x, n and I.

Lemma 5.6  If F is free for x in F, then \( \text{sk}(F)<x, n> = \text{sk}(F<x, n>) \) for all F, x and n.

Lemma 5.7  If F has no \( \mu \)-operators and \( \text{ef}^*(G) \rightarrow \text{ef}^*(H) \), then
\( \text{ef}^*(F[G/x]_F) \rightarrow \text{ef}^*(F[H/x]_F) \) for all F, G, H, x and *.

Hence, if F has no \( \mu \)-operators and \( \text{ef}^*(G) \leftrightarrow \text{ef}^*(H) \), then
\( \text{ef}^*(F[G/x]_F) \leftrightarrow \text{ef}^*(F[H/x]_F) \).

Lemma 5.8  If F has no \( \mu \)-operators, then \( \text{ef}^*(F<x, n+1>) \rightarrow \text{ef}^*(F<x, n>) \)
for all F, x and n.

Lemma 5.9  If F has no \( \mu \)-operators, then \( \text{ef}^*(F<x, n>) \leftrightarrow \text{ef}^*(F<x, 2>) \)
for all \( n \geq 3 \).

Lemma 5.10  If F is free for any free x in F and \( \text{ef}^*(F) \), then
\( F^*_I(t) = I \) for all F, t, * and I.

Proposition 5.11  If \( \text{ef}^+(F) \) and \( \text{ef}^+(F) \), then \( F \cong 0 \).

Thus, the axioms A1 to A6 are valid.
In order to demonstrate the validity of A7, we need to define the monotonic and continuous properties of schemes [12][13].

A function $\phi : D_I \rightarrow D_I$ is said to be monotonic, when, if $s \leq t$, then $\phi(s) \leq \phi(t)$ for all $s$ and $t$. $F_I$ is also said to be monotonic if $F_I$ and $F_I^+$ are monotonic.

**Lemma 5.12** For any $F$ and $I$, $F_I$ is monotonic.

**Lemma 5.13** $F_I, x, n \leq F_I, x, n+1$ for all $I$, $x$, $F$ and $n$.

A function $\phi : D_I \rightarrow D_I$ is said to be continuous if $s_0 \leq s_1 \leq \ldots \leq s_m \ldots$, then $\bigcup_{m=0}^{\infty} \phi(s_m) = \phi(\bigcup_{m=0}^{\infty} s_m)$ for all $s_0, s_1, \ldots$.

**Proposition 5.14** If $F$ is free for $x$ in $F$, then $\mu F \simeq F[\mu F/x]_\sigma$ for any $F$, $G$, $H$, $*$ and $x$.

**Lemma 5.15** If $b_1^*(G)$, then $G*F[H/x]_{b_1} \simeq G*F[(G*H)/x]_{b_1}$ for any $F$, $G$, $H$, $*$ and $x$.

**Lemma 5.16** $F[F[0/x]_{b_1}[G/x]_\sigma]_{b_1} \simeq F[0/x]_{b_1}$ for any $F$, $G$, $*$ and $x$.

**Proposition 5.17** $\mu x F \simeq \mu x (F[0/x]_{b_1})$ for any $F$ and $x$.

### 5.3 Validity of Rules

We will show that the rules of inference in $K$-system preserve validity of equations.

**Proposition 5.18** If $F \not\simeq G$, then $H[G/F] \not\simeq H$ for any $F$, $G$ and $H$.

**Lemma 5.19** If $G \leq_{en} F$, then $F_1^* = G_1^* \ast F[1/G]_I \ast G_1^* \ast F[1/G]_I^*$ for any $F$, $G$, $*$ and $I$, where $\ast$ means the concatenation operation of strings.

**Proposition 5.20** If $H \leq_{en} F$, $H \leq_{en} G$, $F[1/H] \simeq G[1/H]$, and $F[I/H] = G[I/H]$, then $F \simeq G$.

**Proposition 5.20** If $H \leq_{en} F$, $H \leq_{en} G$, $ef^+(H)$ and $F[1/H] \simeq G[1/H]$, then $F \simeq G$. 
Proposition 5.20'  If $H \leq_{en} F$, $H \leq_{en} G$, $ef'(H)$ and $F[I/H] \not\equiv G[I/H]$, then $F \not\equiv G$.

Lemma 5.21

$$F_1^\ast(t) = \begin{cases} F[I/p]_{bl}^\ast(t), & \text{if } F(p)(t) \\ F[I/p]_{bl}^\ast(t), & \text{if } \neg F(p)(t) \end{cases}$$

for any $F$, $I$, $*$, $t$ and $p \in P$.

Proposition 5.22  If $F[I/p]_{bl} \not\equiv G[I/p]_{bl}$ and $F[I/p]_{bl} \not\equiv G[I/p]_{bl}$, then $F \not\equiv G$.

We have a one-side result for $R^4$ as follows:

Lemma 5.23  If $F$ is free for $x$ in $G[x/F]$, $x$ is not a free variable of $G$ and $F \not\equiv G$, then $\mu xG[x/F]_I \notin F_I$ for any $F$, $G$, $x$ and $I$.

We have to prove the converse using the notion of length.

The generalized Herbrand universe of $K$ is the set of all strings $GH_K$ generated by $A \cup \{P^-, P^+ | p \in P\}$ and $\bot$. Suppose we are given a generalized Herbrand interpretation $I = (GH_K, A, P, V)$. In case $t \neq \bot$, let $lg(t)$ denote the number of occurrences of function symbols in $t$.

In a generalized Herbrand interpretation, we redefine the semantics (5.3) and (5.4) as follows:

$$(5.3)' \quad f_I(t) = (tf, \bot)$$

$$(5.4)' \quad p_I(t) = (tp^-, tp^+)$$

We assume that $GH_K$ is closed under the $l, u, b$, operation $\cup$ among strings.

Example 5.2  Schemes $pf+g$, $q(pf+g)$ and $\mu x(pfx)$ in Example 5.1 are interpreted under a generalized Herbrand interpretation as follows:

$$\begin{align*}
(fp+g)_I(t) &= (tp'f \cup tp+g, \bot) \\
(q(pf+g))_I(t) &= (tq'p'f \cup tq'p^+g, tg^+) \\
(\mu x(pfx))_I(t) &= (\bot, \bigcup_{n=0}^\infty t(p^f)^n p^+) 
\end{align*}$$
In a generalized Herbrand interpretation $I$, if we define

$$tp^- = \begin{cases} t, & \text{if } P(p)(t) \\ \bot, & \text{if } \neg P(p)(t) \end{cases}$$

(5.10)  

$$tp^+ = \begin{cases} t, & \text{if } \neg P(p)(t) \\ \bot, & \text{if } P(p)(t), \end{cases}$$

(5.11)  

then the semantics of the $K$-schemes are the same as those defined in Section 5.1.

If $t$ is a string in $GH_K$, let $\lg(t)$ denote the number of occurrences of function symbols in $t$. Suppose $u \in GH_K$ is the $1,u,b$, of a set $S_u$ of strings in $GH_K$. Then $u^{(k)}$ denotes $\bigcup \{ t \in S_u \mid \lg(t) = k \}$, clearly $u = \bigcup_{k=0}^{\infty} u^{(k)}$.

**Lemma 5.24** $\bigcup_{m \leq k} (s^{(m)}(t^{(m)}) \bigcup_{m \leq k} t^{(m)})$ for any $s$, $t$, and $k$.

**Lemma 5.25** $\bigcup_{m \leq k} F_I(t^{(m)}) \subseteq F_I(\bigcup_{m \leq k} t^{(m)})$ for any $F$, $t$, $k$ and $I$.

**Lemma 5.26** If $rg^*(F)$, then

$$F^*_I(t)(0) = \bot$$

$$\bigcup_{m \leq k+1} F^*_I(t^{(m)}) \subseteq F^*_I(\bigcup_{m \leq k} t^{(m)})$$

for any $F$, $t$, $*$ and $I$.

**Lemma 5.27** If $F$ is free for $x$ in $G[x/F]$, then $\bigcup_{m \leq k} G_I(t^{(m)}) \subseteq (G[x/F] \mid \bigcup_{m \leq k} F_I(t^{(m)}/x)(t))$, $k=1, 2, \ldots$ for any $F$, $G$, $x$, $I$ and $t$.

**Proposition 5.28** If $F$ is free for $x$ in $G[x/F]$, $x$ is not a free variable in $F$ and $F \not\equiv G$, then $F \not\equiv \mu x G[x/F]_{rg}$ for any $F$, $G$, $x$.

This concludes the proof that all rules on inferences $R1 \sim R4$ preserves the validity of equations.
