ARCHIMEDEAN CLASSES IN AN ORDERED SEMIGROUP IV

Tôru Saitô

By an ordered semigroup we mean a semigroup $S$ with a simple order $\leq$ which satisfies

for $x, y, z \in S$, $x \leq y$ implies $xz \leq yz$ and $zx \leq zy$.

The archimedean equivalence $A$ on an ordered semigroup $S$ is defined by:

for $x, y \in S$, $xA y$ if and only if there exist natural numbers $p, q, r$ and $s$ such that $x^p \leq y^q$ and $y^r \leq x^s$.

The difficulty occurs because of the fact that the archimedean equivalence is not necessarily a congruence relation. In our previous papers [3], [4] and [5], we discussed the behavior of set products of two archimedean classes of an ordered semigroup. The purpose of the present paper is to give some supplementary properties to preceding papers and also some applications.

We use the terminology and notations in our previous papers [3], [4] and [5] freely.

1. In this section, we give some properties of archimedean classes which will be needed in the following discussion.

LEMMA 1. Suppose $A, B \subseteq C$, $B^\delta \leq A^\delta$ and $B^\delta$ is periodic of L-type. Let $g$ be the idempotent of $A \ast B$ and $f$ the idempotent of $B$. Then

(1) $ag = g$ for every $a \in A$;

(2) if $B^\delta < A^\delta$, then $af = g$ for every $a \in A$.

*) In the seminar, we gave a talk which covers our papers "Archimedean classes in an ordered semigroup I-IV". But Part I-III was published recently and, accordingly, we publish here only Part IV.
PROOF. Since \((A * B)\delta = A\delta \land B\delta = B\delta\), \(A * B\) is a periodic archimedean class and so really contains the unique idempotent \(g\).

In the proof, we only consider the case when \(A \leq B\). Then \(A \leq A * B \leq B\). First suppose that \(B\delta = A\delta\). Then

\[
A * B = \min\{x \in C ; A \leq x \leq B \text{ and } x \in A\delta \land B\delta = A\delta\} = A.
\]

Since \(g\) is the zero element of \(A * B = A\), we have \(ag = g\) for every \(a \in A\). Next suppose that \(B\delta < A\delta\). Let \(a \in A\) and put \(h = ag\). Let \(D\) be the archimedean class containing the element \(h\).

Then, by [3] Lemma 5.2, \(h\) is an idempotent and

\[
D = \min\{x \in C ; A \leq x \text{ and } x \in B\delta\}.
\]

Since \(A < A * B\) and \((A * B)\delta = A\delta \land B\delta = B\delta\), we have \(D \leq A * B\).

On the other hand, \(h = ag \leq f^2 = f\) and so \(A \leq D \leq B\) and also \(D \in B\delta = A\delta \land B\delta\). Hence \(A * B \leq D\) and so \(D = A * B\). Hence \(h = g\) and so \(ag = g\). Moreover, since \(A < A * B\), we have \(a < g\). Hence

\[
g = ag \leq af \leq gf = g
\]

and so \(af = g\).

THEOREM 2. Suppose that \(A, B \in C\), \(A\delta \land B\delta < A\delta\) and \(A\delta \land B\delta\) is periodic of \(L\)-type. Then

1. if \(A \leq B\), then \(AB \subseteq (A * B)_+\);

2. if \(B \leq A\), then \(AB \subseteq (A * B)_-\).

PROOF. Here we only show the assertion (1). Suppose \(A \leq B\).

Since \(A\delta \land B\delta < A\delta\), we have \(A < A * B \leq B\). Since \((A * B)\delta = A\delta \land B\delta\), \(A * B\) is a periodic archimedean class. We denote by \(g\) the idempotent of \(A * B\). Let \(a \in A\) and \(b \in B\). First suppose \(g \leq b\). Then, since \(a < g\), we have \(ab \leq gb = g\). On the other hand, \((A * B)\delta = A\delta \land B\delta < A\delta\) and, by [3] Lemma 5.10, \(A * (A * B) = A * B\). Hence, by Lemma 1, \(g = ag \leq ab\). Hence \(ab = g \in (A * B)_+\). Next suppose that \(b \leq g\). Then we have \(B \leq A * B\) and so \(B = A * B\). Hence \(B\) is a periodic archimedean class with idempotent \(g\) and so \(b^n = g\) for some natural number \(n\). Hence if \(ab \leq ba\), then, by Lemma 1,
\[ g = a^{n+1}g = a^{n+1}b^{n+1} \leq (ab)^{n+1} \leq ab^n a^n b = aga^n b = ag = g, \]
and if \( ba \leq ab \), then
\[ g = ag = aga^n b = ab^n a^n b \leq (ab)^{n+1} \leq a^{n+1}b^{n+1} = a^{n+1}g = g. \]
Thus we have \((ab)^{n+1} = g\) and so \( ab \in A \ast B \). Also, since \( A < A \ast B \), we have \( ab \leq gb = g \) and so \( ab \in (A \ast B)_+ \).

In the proof of Theorem 2, we incidentally proved

**COROLLARY 3.** Suppose that \( A, B \in C, A \delta \land B \delta < A \delta, A \delta \land B \delta \)
is periodic of \(L\)-type and \( A \leq B \). Let \( g \) be the idempotent of \( A \ast B \). Then \( ab = g \) for every \( a \in A \) and \( b \in B \) such that \( g \leq b \).
In particular, if \( A \ast B \neq B \), then \( ab = g \) for every \( a \in A \) and \( b \in B \).

2. Let \( S \) be an ordered semigroup. \( S \) is called \( a\)-regular if the archimedean equivalence on \( S \) is a congruence relation. \( S \) is called \( \text{nongnegatively ordered} \) if \( a \leq a^2 \) for every \( a \in A \).
A criterion of \( a\)-regularity for a nongnegatively ordered semigroup was given in [2] Theorem 2.8. The purpose of this section is to give a criterion of \( a\)-regularity for a general ordered semigroup.

The next Lemma was given in our Lecture Note [6]. But, for the sake of convenience we give it with proof.

**LEMMA 4.** Let \( a \) be an element of \( n \) of an ordered semigroup \( S \). If there exists an idempotent \( g \) of \( S \) such that \( a^n D g \) and \( a \) lies between \( a^n \) and \( g \), then \( n \leq 2 \).

**PROOF.** Suppose \( n < 1 \). We consider only the case when \( a \) is positive, that is, \( a < a^2 \). Then we have \( g < a < a^2 \leq a^n \). By [3] Lemmas 1.6 and 1.7, we have \( a^n L g \) or \( a^n R g \). For the sake of definiteness, we assume \( a^n R g \) and so \( a^n g = g \), \( ga^n = a^n \).
Then \( g = g^2 \leq ag \leq a^n g = g \) and so \( g = ag \). Hence \( g a = ga \) and \( g a^2 g a^2 = g a^2 \) and so \( ga \) and \( ga^2 \) are idempotents of \( S \). We have \( a < ga^2 \), since \( ga^2 \leq a \) would imply \( a^n = ga^n \leq \ldots \leq ga^2 \leq a \),
which is a contradiction. If \( a \preceq g a \), then
\[
a^3 \preceq (g a)^3 = g a^2 \preceq a^3,
\]
and if \( g a \preceq a \), then
\[
a^3 \preceq (g a^2)^3 = g a^2 = (g a)a \preceq a^2 \preceq a^3.
\]
Hence, in both cases, we have \( a^2 = a^3 \).

**THEOREM 5.** The archimedean equivalence in an ordered semigroup
S is not a congruence relation, if and only if either

(1) there exist torsion-free archimedean classes \( A \) and \( B \) in \( S \) such that \( A \neq B \) and \( A \Join B \), or

(2) \( S \) contains a subsemigroup \( o \)-isomorphic to either one of
the ordered semigroups \( K_1, K_2, K_3 \) and \( K_4 \):

\[
\begin{array}{ccc}
  e & f & a & g \\
  K_1: & e & e & e & e & e \\
  f & f & f & f & f \\
  a & f & g & g & g \\
  g & g & g & g & g \\
\end{array}
\quad
\begin{array}{ccc}
  e & f & a & g \\
  K_2: & e & e & f & f & g \\
  f & e & f & g & g \\
  a & e & f & g & g \\
  g & e & f & g & g \\
\end{array}
\]

\[
\begin{array}{c}
  e < f < a < g \\
\end{array}
\quad
\begin{array}{c}
  e < f < a < g \\
\end{array}
\]

\[
\begin{array}{ccc}
  g & a & f & e \\
  K_3: & g & g & g & g \\
  a & g & g & g & f \\
  f & f & f & f & f \\
  e & e & e & e & e \\
\end{array}
\quad
\begin{array}{ccc}
  g & a & f & e \\
  K_4: & g & g & g & f \\
  a & g & g & f & e \\
  f & g & g & f & e \\
  e & g & f & f & e \\
\end{array}
\]

\[
\begin{array}{c}
  g < a < f < e \\
\end{array}
\quad
\begin{array}{c}
  g < a < f < e \\
\end{array}
\]

**PROOF.** "Only if" part. Suppose that the archimedean equivalence on \( S \) is not a congruence relation. Then there exist archimedean classes \( A \) and \( B \) such that \( A \Join B \) is not contained in a single archimedean class. First suppose that \( A \Join \ \Join B \) is torsion-free.
Then, by [3] Corollary 6.2, we have $A \neq B$ and $A \delta B$. Then
$A \delta = A \delta \land B \delta = B \delta$ and so $A$ and $B$ are torsion-free archimedean
classes. Hence we have the condition (1). Next suppose that $A \delta \land B \delta$
is periodic. First we consider the case when $A \delta \land B \delta$ is of L-type
and $A \leq B$. Then, by Theorem 2, we have $A \delta = A \delta \land B \delta$. We denote
by $g$ and $e$ the idempotents of the periodic archimedean classes
$A$ and $B \ast A$, respectively. Then $A \delta = A \delta \land B \delta = (B \ast A) \delta$ and,
by [3] Theorem 3.3, we have $g D_E e$. Also, by [3] Lemma 6.7, there
exists an idempotent $f$ of $S$ such that $g < f < e$ and $g D_E f$,
and also there exists $a \in A \setminus \{g\}$ such that $ae = f$. Since $A$
is a periodic archimedean class with idempotent $g$, we have $a^n = g$
for some natural number $n > 1$. Also $g = a^n < a < f$ and, by Lemma 4,
we have $a^2 = g$. Now we can verify that $(g, a, f, e)$ forms a sub-
semigroup o-isomorphic to $K_3$. In a similar way, if $A \delta \land B \delta$ is of
L-type and $B \leq A$ or $A \delta \land B \delta$ is of R-type and $A \leq B$ or $A \delta \land B \delta$
is of R-type and $B \leq A$, we can prove that $S$ contains a subsemigroup
o-isomorphic to $K_1$ or $K_2$ or $K_4$.

"If" part. Suppose that there exist torsion-free archimedean
classes $A$ and $B$ in $S$ such that $A \neq B$ and $A \delta B$. Then,
by [3] Theorem 2.4, $AB \cap A \neq \emptyset$ and $AB \cap B \neq \emptyset$. Hence $AB$ is not
contained in a single archimedean class and so the archimedean equi-
valence is not a congruence relation. If $S$ contains a subsemigroup
o-isomorphic to $K_1$ or $K_2$ or $K_3$ or $K_4$, then clearly the archi-
medean equivalence is not a congruence relation.

3. As an application, in this section we give a result that
a finite product of elements of an ordered semigroup is archimedean
equivalent under certain conditions to a product of at most two of
these factors.
LEMMA 6. In an ordered semigroup \( S \), let \( a = x_1 \ldots x_n \) and let \( X_1, \ldots, X_n \) and \( A \) be archimedean classes containing \( x_1, \ldots, x_n \) and \( a \), respectively. Then
\[
X_1^\delta \land \ldots \land X_n^\delta \leq A^\delta.
\]

PROOF. If \( n = 1 \), the assertion is trivial. Suppose \( n = 2 \).

If \( x_1 \leq x_2 \), then
\[
x_1^2 \leq x_1 x_2 = a \leq x_2^2 \quad \text{with} \quad x_1^2 \in X_1, \quad a \in A \quad \text{and} \quad x_2^2 \in X_2.
\]
and if \( x_2 \leq x_1 \), then
\[
x_2^2 \leq x_1 x_2 = a \leq x_1^2 \quad \text{with} \quad x_2^2 \in X_2, \quad a \in A \quad \text{and} \quad x_1^2 \in X_1.
\]
Hence, by [3] Lemma 5.6, we have \( X_1^\delta \land X_2^\delta \leq A^\delta \). Suppose \( n > 2 \).

Put \( y = x_2 \ldots x_n \) and let \( Y \) be the archimedean class containing \( y \).

Then, by induction hypothesis,
\[
X_2^\delta \land \ldots \land X_n^\delta \leq Y^\delta
\]
and, since \( a = x_1 x_2 \ldots x_n = x_1 y \), we have
\[
X_1^\delta \land X_2^\delta \land \ldots \land X_n^\delta \leq X_1^\delta \land Y^\delta \leq A^\delta.
\]

THEOREM 7. In an ordered semigroup \( S \), let \( a = x_1 \ldots x_n \) and let \( X_1, \ldots, X_n \) and \( A \) be archimedean classes containing \( x_1, \ldots, x_n \) and \( a \), respectively. If \( X_1^\delta \land \ldots \land X_n^\delta = A^\delta \) and \( a \) is an element of infinite order, then \( a \land x_i \) for some \( 1 \leq i \leq n \).

PROOF. If \( n = 1 \), then the assertion is trivial. Suppose \( n = 2 \). If \( X_1 = X_2 \), then \( a = x_1 x_2 \in X_1 X_2 = X_1^2 \subseteq X_1 \) and so \( a \land x_1 \).

If \( X_1 \neq X_2 \) and \( X_1^\delta = X_2^\delta \), then \( A^\delta = X_1^\delta \land X_2^\delta = X_1^\delta = X_2^\delta \) and, by [3] Theorem 3.5, \( A = X_1 \) or \( A = X_2 \). Hence we have \( a \land x_1 \) or \( a \land x_2 \).

If \( X_1^\delta \neq X_2^\delta \), then, since \( X_1^\delta \land X_2^\delta = A^\delta \) is a torsion-free \( \delta \)-class, it follows from [3] Theorem 6.1 that either \( a = x_1 x_2 \in X_1 X_2 \subseteq X_1 \) or \( a = x_1 x_2 \in X_1 X_2 \subseteq X_2 \) and so \( a \land x_1 \) or \( a \land x_2 \).

Finally suppose \( n > 2 \). Let \( Y \) be the archimedean class containing the element \( y = x_2 \ldots x_n \). Then, since \( a = x_1 x_2 \ldots x_n = x_1 y \), we have \( X_1^\delta \land Y^\delta \leq A^\delta \) and \( X_2^\delta \land \ldots \land X_n^\delta \leq Y^\delta \) by Lemma 6. Hence
\[
A^\delta = X_1^\delta \land X_2^\delta \land \ldots \land X_n^\delta \leq X_1^\delta \land Y^\delta \leq A^\delta.
\]
and so \( X \delta \wedge Y \delta = A \delta \). Also we have \( a = x_1 y \) and so \( a \wedge x_1 \) or \( a \wedge y \). But, if \( a \wedge y \), then we have \( A = Y \) and so

\[
Y \delta = A \delta = X_1 \delta \wedge X_2 \delta \wedge \ldots \wedge X_n \delta \leq X_2 \delta \wedge \ldots \wedge X_n \delta \leq Y \delta.
\]

Hence \( Y \delta = X_2 \delta \wedge \ldots \wedge X_n \delta \) and, by induction hypothesis, we have a \( A \wedge Y \wedge x_i \) for some \( 2 \leq i \leq n \). This completes the proof.

**Lemma 8.** Let \( A, B \) and \( C \) be Archimedean classes in an ordered semigroup \( S \) such that \( AB \subseteq C \). Then we have \( C = A \ast B \) and \( C \delta = A \delta \wedge B \delta \).

**Proof.** If \( A = B \), then \( AB = A^2 \subseteq A \) and so \( C = A \). Hence, by [3] Lemma 5.8, \( C = A = A \ast A = A \ast B \) and also \( C \delta = A \delta = A \delta \wedge B \delta \). Next suppose that \( A \neq B \) and \( A \delta \wedge B \delta \) is torsion-free. Then, by [3] Corollary 6.2, \( A \delta \wedge B \delta \) does not hold. Hence, by [3] Theorem 6.1, we have either \( A \gamma B \) or \( B \gamma A \). Also, if \( A \gamma B \), then, since \( AB \subseteq A = A \ast B \), we have \( C = A = A \ast B \) and \( C \delta = A \delta = A \delta \wedge B \delta \), and if \( B \gamma A \), then, since \( AB \subseteq B = A \ast B \), we have \( C = B = A \ast B \) and \( C \delta = B \delta = A \delta \wedge B \delta \). Finally suppose that \( A \neq B \) and \( A \delta \wedge B \delta \) is periodic. For the sake of definiteness we assume \( A \leq B \) and \( A \delta \wedge B \delta \) is of \( L \)-type. Let \( a \in A \) and \( b \in B \). Then, since \( A < B \), we have \( a < b \) and so \( a^2 \leq ab \leq b^2 \) with \( a^2 \in A \), \( ab \in C \) and \( b^2 \in B \). Hence \( A \leq C \leq B \) and, by [3] Lemma 5.6, we have \( A \delta \wedge B \delta \leq C \delta \). On the other hand, we have \( a^2 b = a(ab) \in C \cap AC \) and \( ab^2 = (ab)b \in C \cap CB \). Hence \( C \wedge A \) and \( C \wedge B \) and so \( C \delta \leq A \delta \wedge B \delta \). Hence we have \( C \delta = A \delta \wedge B \delta \). Also, since \( A \leq C \leq B \) and \( C \in A \delta \wedge B \delta \), we have

\[
A \ast B = \min \{ D \in C ; A \leq D \leq B \text{ and } D \in A \delta \wedge B \delta \} \leq C.
\]

On the other hand, since \( A \ast B \in A \delta \wedge B \delta \), \( A \ast B \) is a periodic Archimedean class and so contains an idempotent, say \( g \). Then, since \( A \leq A \ast B \), we have \( a_1 \leq g \) for some \( a_1 \in A \). Since \( (A \ast B) \delta = A \delta \wedge B \delta \leq B \delta \), we have \( (A \ast B) \gamma B \) and so, by [3] Theorem 2.7, \( a_1 b \leq gb = g \). Hence we have \( C \leq A \ast B \) and thus \( C = A \ast B \).
LEMMA 9. In a nonnegatively ordered semigroup $S$, suppose that $a = x_1 \ldots x_n$. Let $x_1, \ldots, x_n$ and $A$ be archimedean classes containing $x_1, \ldots, x_n$ and $a$, respectively. Then $x_1^\delta \wedge \ldots \wedge x_n^\delta = A^\delta$.

PROOF. If $n = 1$, the assertion is trivial. Suppose $n = 2$. If $x_1x_2$ is contained in a single archimedean class, then, by Lemma 8, we have $x_1^\delta \wedge x_2^\delta = A^\delta$. Next consider the case when $x_1x_2$ is not contained in a single archimedean class. If $x_1 \leq x_2$, then, since $S$ is nonnegatively ordered, it follows from [3] Lemma 1.8 that $x_2$ is a periodic archimedean class of $R$-type with idempotent, say $e$, and there exists an idempotent $f$ such that $f \not= e$ and $x_1x_2 \subseteq \{f\} \cup x_2$. We denote by $Y$ the archimedean class containing the element $f$. Then, by [3] Theorem 3.3, we have $Y^\delta = x_2^\delta$. Since $a = x_1x_2 \in \{f\} \cup x_2$, we have $A^\delta = x_2^\delta$. On the other hand,

$$x_1e = x_1(x_2e) = x_1x_2e \in \{f\} \cup x_2 \cap \{e\} \cup x_2 \{e\} = \{e\},$$

and so $e = x_1e \in x_1x_2 \cap x_2$. Hence $x_2 \gamma x_1$ and so $x_2^\delta \leq x_1^\delta$.

Hence we have $A^\delta = x_2^\delta = x_1^\delta \wedge x_2^\delta$. If $x_2 \leq x_1$, we can similarly prove that $A^\delta = x_1^\delta \wedge x_2^\delta$.

Now suppose $n > 2$. We put $y = x_2 \ldots x_n$ and denote by $Z$ the archimedean class containing $y$. Then, by induction hypothesis, $Z^\delta = x_2^\delta \wedge \ldots \wedge x_n^\delta$. Also, since $a = x_1x_2 \ldots x_n = x_1y$, we have $A^\delta = x_1^\delta \wedge Z^\delta$. Hence

$$A^\delta = x_1^\delta \wedge x_2^\delta \wedge \ldots \wedge x_n^\delta.$$

COROLLARY 10. In a nonnegatively ordered semigroup $S$, suppose that $a = x_1 \ldots x_n$ and $a$ is an element of infinite order. Then $a \wedge x_i$ for some $1 \leq i \leq n$. 

LEMMA 11. In an ordered semigroup \( S \), let \( a = x_1 x_2 x_3 \) and let \( x_1, x_2, x_3 \) and \( A \) be archimedean classes containing \( x_1, x_2, x_3 \) and \( a \), respectively. If \( A \delta \) is periodic of \( L \)-type and \( x_1 \delta \land x_2 \delta \land x_3 \delta = A \delta \land x_1 \delta \land x_2 \delta \), then \( a \) is \( A x_1 x_3 \) or \( A x_2 x_3 \).

PROOF. Put \( y = x_1 x_2 \) and let \( Y \) be the archimedean class containing \( y \). Then, by Lemma 6, \( X_1 \delta \land x_2 \delta \leq Y \delta \) and, since \( a = x_1 x_2 x_3 = y x_3 \), we also have \( Y \delta \land x_3 \delta \leq A \delta = x_1 \delta \land x_2 \delta \land x_3 \delta \leq X_1 \delta \land x_3 \delta \). Hence

\[
Y \delta \land x_3 \delta = A \delta \land x_1 \delta \land x_2 \delta \leq Y \delta.
\]

Hence, by Theorem 2, \( a = y x_3 \in Y \ast X_3 \). Now, by way of contradiction, we assume that \( x_3 \) lies between \( x_1 \) and \( x_2 \), that is, either \( x_1 \leq x_3 \leq x_2 \) or \( x_2 \leq x_3 \leq x_1 \). Then we have either \( X_1 \leq X_3 \leq X_2 \) or \( X_2 \leq X_3 \leq X_1 \). Hence, by (3) Lemma 5.6, we have \( X_1 \delta \land x_2 \delta \leq X_3 \delta \) and so \( X_1 \delta \land x_2 \delta \land x_3 \delta = X_1 \delta \land x_2 \delta \), which is a contradiction.

Hence either \( x_1 \) lies between \( x_2 \) and \( x_3 \) or \( x_2 \) lies between \( x_1 \) and \( x_3 \). For the sake of definiteness, we assume \( x_2 \leq x_1 \leq x_3 \). Then \( X_2 \leq X_1 \leq X_3 \) and, by (3) Lemma 5.6, we have \( X_2 \delta \land x_3 \delta \leq X_1 \delta \) and so \( X_2 \delta \land x_3 \delta = X_1 \delta \land x_2 \delta \land x_3 \delta = A \delta \land x_1 \delta \land x_2 \delta \leq X_2 \delta \). Hence, by Theorem 2, \( x_2 x_3 \in X_2 \ast X_3 \). Now, since \( x_2 \leq x_1 \), we have \( x_2^2 \leq x_1 x_2 \leq x_1^2 \) and so \( x_2 \leq y \leq x_1 \leq x_3 \). Also, for every \( Z \in C \) such that \( X_2 \leq Z \leq Y \), we have \( X_2 \leq Z \leq Y \leq X_1 \) and, again by (3) Lemma 5.6, \( X_2 \delta \land x_3 \delta = A \delta \land x_1 \delta \land x_2 \delta \leq Z \delta \). Hence

\[
Y \ast X_3 = \min\{ U \in C ; \ Y \leq U \leq X_3 \text{ and } U \in A \delta \}
\]

\[
= \min\{ U \in C ; \ X_2 \leq U \leq X_3 \text{ and } U \in A \delta \} = X_2 \ast X_3.
\]

Thus we obtain \( a = x_2 x_3 \in Y \ast X_3 = X_2 \ast X_3 \) and so \( a \) is \( A x_2 x_3 \). In the remaining cases, we can similarly prove that either \( a \) is \( A x_1 x_3 \) or \( a \) is \( A x_2 x_3 \).
LEMMA 12. In a nonnegatively ordered semigroup $S$, suppose that $A, B \in C$ such that $A\delta \leq B\delta$ and $A\delta$ is periodic of $L$-type and $a \in A$, $b \in B$ and $e$ and $g$ are idempotents of the periodic archimedean classes $A$ and $B * A$, respectively. Then $ab \in A$ if and only if $ag = e$.

PROOF. First suppose that $AB \subseteq A$. Then we have $ab \in A$ for every $a \in A$ and $b \in B$. On the other hand, if $A = B * A$, then we have $ag = ae = e$. Also, if $A \neq B * A$, then, since $B * A$ lies between $A$ and $B$, the element $g$ in $B * A$ lies between $a$ and $b'$ for some $b' \in B$. Hence $ag$ lies between $a^2$ and $ab'$ with $a^2 \in A$ and $ab' \in AB \subseteq A$. Hence $ag \in A$ and, since $(B * A)\delta = A\delta \wedge B\delta = A\delta$, we have $ga = g$ by [3] Theorem 2.7 and so $ag$ is an idempotent of $A$. Hence $ag = e$. Next suppose that $AB$ is not contained in $A$. Since $eb = e \in AB \cap A$, $AB$ is not contained in a single archimedean class. Hence, by [3] Lemma 1.8, $B < A$ and $AB \subseteq \{f\} \cup A$, where $f$ is an idempotent of $S$ such that $f < e$ and $f \notin e$. Again by [3] Lemma 1.8, $BA$ is contained in a single archimedean class and, by Lemma 8, $BA \subseteq B * A$. Since $be$ is an idempotent and also $be \in BA \subseteq B * A$, we have $be = g$. Now we suppose $ab \in A$. Then $ag = a(be) = (ab)e = e$. Next we suppose $ab \notin A$. Then, since $ab \in AB \subseteq \{f\} \cup A$, we have $ab = f$. Hence $ag = a(be) = (ab)e = fe = f \neq e$.

LEMMA 13. In a nonnegatively ordered semigroup $S$, let $a = x_1x_2x_3$ and let $X_1, X_2, X_3$ and $A$ be archimedean classes containing $x_1, x_2, x_3$ and $a$, respectively. If $A\delta$ is periodic, then $a = A x_1x_2$ or $a = A x_2x_3$ or $a = x_1x_3$.

PROOF. For the sake of definiteness we assume $A\delta$ is of $L$-type. By Lemma 9, we have $A\delta = X_1\delta \wedge X_2\delta \wedge X_3\delta$. If $A\delta < X_1\delta \wedge X_2\delta$, then the assertion follows from Lemma 11. In what follows, we assume
Aδ = X_1δ ∧ X_2δ. We denote by Y the archimedean class containing x_1x_2. By Lemma 9, Yδ = X_1δ ∧ X_2δ = Aδ and so Y is a periodic archimedean class with idempotent, say e. If x_1x_2x_3 ∈ Y, then we clearly have a = x_1x_2x_3 ∧ α x_1x_2. Suppose x_1x_2x_3 ∉ Y. Then, since e = ex_3 ∈ Y ∩ YX_3, YX_3 does not contain in a single archimedean class. Hence, by [3] Lemma 1.8, we have X_3 < Y, every element of Y is of order at most two, there exists an idempotent f of S such that f < e, f ∉ L e and e and f are consecutive in eL, there exists a periodic archimedean class U with idempotent g which satisfies g ∈ L e, g < e, X_3 ≤ U, x_3U, UX_3 ⊆ U, Yg = {f, e} and YX_3 ⊆ {f} ∪ Y. Since x_1x_2x_3 ∈ YX_3 and x_1x_2x_3 ∉ Y, we have x_1x_2x_3 = f.

(a) The case: X_1 ≤ X_2.

Since X_1δ ∧ X_2δ = Aδ is of L-type, X_1X_2 is contained in a single archimedean class by [3] Lemma 1.8. Hence, by Lemma 8, X_1 ≤ Y = X_1X_2 ≤ X_2. Since

X_1X_2 = \min\{X ∈ C ; X_1 ≤ X ≤ X_2 \text{ and } X ∈ X_1δ ∧ X_2δ = Aδ\},

there is no archimedean class X ∈ Aδ such that X_1 ≤ X ≤ Y. Since e ∈ Y and Yδ = X_1δ ∧ X_2δ = Aδ, we have eX_1 = e and so x_1e is an idempotent and x_1e ∈ L e. Since S is nonnegatively ordered, e is the greatest element of Y and so X_1 ≤ e. Hence x_1^2 ≤ x_1e ≤ e and so the archimedean class containing x_1e belongs to Aδ and lies between X_1 and Y. Hence it coincides with Y and so x_1e = e. Now, since g ∈ L e, we have Uδ = Yδ = Aδ ⊆ X_3δ and so gx_3 = g by [3] Lemma 2.7. Hence x_3g is an idempotent and also x_3g ∈ X_3U ⊆ U. Hence x_3g = g and so x_1x_2g = x_1x_2x_3g = fg = f < e = x_1e. Hence x_2g < e = eg and so x_2 < e. Hence X_2 ≤ Y ≤ X_2 and so we obtain X_2 = Y. Since X_3U ⊆ U, it follows from Lemma 8 that U = X_3 * U. Also, since X_3 ≤ U < Y = X_2, Uδ = Aδ and (X_3 * X_2)δ = X_3δ ∧ X_2δ = Aδ,
\[ U = X_3 \star U = \min \{ X \in C ; \ X_3 \leq X \leq U \ \text{and} \ X \in A \delta \} \]

\[ = \min \{ X \in C ; \ X_3 \leq X \leq X_2 \ \text{and} \ X \in A \delta \} = X_3 \star X_2 \]

and so \( q \) is the idempotent of \( X_3 \star X_2 \). Now \( e \) is the idempotent of \( X_2 \) and \( x_2 \bar{g} \neq e \), it follows from Lemma 12 that \( x_2 x_3 \not\in X_2 \).

Hence \( X_2 X_3 \) is not contained in a single archimedean class and, by \( [3] \) Lemma 1.8, we have \( x_2 x_3 = f \) and so \( x_2 x_3 = f = x_1 x_2 x_3 = a \).

(b) The case: \( X_2 \preceq X_1 \) and \( X_1 X_2 \) is contained in a single archimedean class.

We have \( X_2 \preceq X_1 \star X_2 \preceq X_1 \) and, by Lemma 8, \( Y = X_1 \star X_2 \).

Also \( x_1 x_2 x_3 = f < e = e x_2 x_3 \) and so \( x_1 < e \). Hence we have \( X_1 \preceq X_1 \star X_2 \) and so \( X_1 = X_1 \star X_2 \). If \( x_2 \preceq x_3 \), then

\[ f = f x_2^2 \preceq x_1 x_2^2 \preceq x_1 x_2 x_3 = f \]

and so \( x_1 x_2^2 = f \not\in X_1 \). Since \( x_1 \delta = (X_1 \star X_2) \delta = X_1 \delta \land X_2 \delta \preceq X_2 \delta \), it follows from Lemma 12 that \( x_1 h \neq e \), where \( h \) is the idempotent of \( X_2 \star X_1 \). Hence, again by Lemma 12, we have \( x_1 x_2 \not\in X_1 \). But, by \( [3] \) Lemma 1.8, \( X_1 X_2 \subseteq \{f\} \cup X_1 \) and so \( x_1 x_2 = f = x_1 x_2 x_3 = a \).

If \( x_3 \preceq x_2 \), we can prove in a similar way that \( a = x_1 x_3 \).

(c) The case: \( X_2 \preceq X_1 \) and \( X_1 X_2 \) is not contained in a single archimedean class.

By \( [3] \) Lemma 1.8, \( X_1 \) is a periodic archimedean class with idempotent, say \( e_1 \), there exists an idempotent \( f_1 \) of \( S \) such that \( f_1 < e_1 \), \( f_1 \mathbin{\Lleftarrow} e_1 \) and \( f_1 \) and \( e_1 \) are consecutive in \( e_1 L \), there exists a periodic archimedean class \( T \) with idempotent \( k \) such that \( k \mathbin{\Lleftarrow} e_1 \), \( X_2 \preceq T \), \( T X_2 \), \( X_2 T \subseteq T \) and \( X_1 X_2 \subseteq \{f_1\} \cup X_1 \).

Hence \( x_1 x_2 \in X_1 X_2 \subseteq \{f_1\} \cup X_1 \). If \( x_1 x_2 = f_1 \), then \( f_1 \) is an idempotent of \( Y \) and so \( x_1 x_2 = f_1 = e \). Hence \( a = x_1 x_2 x_3 = e \neq f \), which is a contradiction. Hence \( x_1 x_2 \in X_1 \). Then we have \( X_1 = Y \) and so \( e_1 = e \), \( f_1 = f \). Since \( X_2 T \subseteq T \), we have \( T = X_2 \star T \) by Lemma 8 and so, since \( T \delta = X_1 \delta = Y \delta = A \delta = X_1 \delta \land X_2 \delta \) and \( X_2 \preceq T < X_1 \),
Let \( T = x_2 \ast T = \min \{ x \in C \mid x_2 \leq x \leq T \text{ and } x \in A \delta \} \)

\[
= \min \{ x \in C \mid x_2 \leq x \leq x_1 \text{ and } x \in A \delta \} = x_2 \ast x_1.
\]

Hence \( k \) is the idempotent of \( x_2 \ast x_1 \) and, since \( x_1 x_2 \in x_1 \), we have \( x_1 k = e \) by Lemma 12. Hence, again by Lemma 12,

\[
x_1 x_2^2 \in x_1 = Y \quad \text{and so} \quad x_1 x_2 x_3 = f < x_1 x_2^2.
\]

Hence we have \( x_3 < x_2 \) and so \( x_1 x_3^2 \leq x_1 x_2 x_3 = f < e \). Since \( X_1 \delta = A \delta \leq X_3 \delta \), it follows from [3] Theorem 2.7 that \( \text{ex}_3 = e \in X_1 x_3 \cup X_1 \). Hence \( X_1 x_3 \) is not contained in a single archimedean class and so, by [3] Lemma 1.8, \( X_1 x_3 \subseteq \{ f \} \cup X_1 \). Since \( x_1 x_3^2 \leq f \), we have \( x_1 x_3^2 \not\in X_1 \) and so \( x_1 h \neq e \) by Lemma 12, where \( h \) is the idempotent of \( X_3 \ast X_1 \).

Hence, again by Lemma 12, \( x_1 x_3 \not\in X_1 \). Since \( x_1 x_3 \in X_1 x_3 \subseteq \{ f \} \cup X_1 \), we have \( x_1 x_3 = f = x_1 x_2 x_3 = a \).

**THEOREM 14.** In a nonnegatively ordered semigroup \( S \), let \( a = x_1 \ldots x_n \) with \( n \geq 2 \) and let \( x_1, \ldots, x_n \) and \( A \) be archimedean classes containing \( x_1, \ldots, x_n \) and \( a \), respectively. If \( a \) is an element of finite order, then \( a \ast x_i x_j \) for some \( i, j \) such that \( 1 \leq i < j \leq n \).

**PROOF.** If \( n = 2 \), the assertion is trivial. If \( n = 3 \), then the assertion is given by Lemma 13. If \( n > 3 \), then put \( y = x_3 \ldots x_n \). Then \( a = x_1 x_2 y \) and, by Lemma 13, \( a \ast x_1 x_2 \) or \( a \ast x_2 y = x_2 x_3 \ldots x_n \) or \( a = x_1 y = x_1 x_3 \ldots x_n \). Now we obtain the assertion by induction hypothesis.

**COROLLARY 15 ([1] Théorème 1).** In an ordered idempotent semigroup \( S \), the product of a finite number of elements of \( S \) is equal to a product of at most two of these factors.

**PROOF.** If \( S \) is an ordered idempotent semigroup, each element is of finite order and each archimedean class is constituted by a single element. Hence the corollary follows from Theorem 14.
COROLLARY 16. In a nonnegatively ordered semigroup $S$, the product of a finite number of elements of $S$ is archimedean equivalent to a product of at most two of these factors.

PROOF. The corollary follows from Corollary 10 and Theorem 14.

Example 17. Let $S$ be an ordered semigroup consisting of seven elements $e < a < u < g < v < b < f$ with the multiplication table:

<table>
<thead>
<tr>
<th></th>
<th>e</th>
<th>a</th>
<th>u</th>
<th>g</th>
<th>v</th>
<th>b</th>
<th>f</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
</tr>
<tr>
<td>a</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>e</td>
<td>a</td>
<td>u</td>
<td>g</td>
</tr>
<tr>
<td>u</td>
<td>e</td>
<td>a</td>
<td>u</td>
<td>g</td>
<td>g</td>
<td>g</td>
<td>g</td>
</tr>
<tr>
<td>v</td>
<td>g</td>
<td>g</td>
<td>g</td>
<td>g</td>
<td>v</td>
<td>b</td>
<td>f</td>
</tr>
<tr>
<td>b</td>
<td>g</td>
<td>v</td>
<td>b</td>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

In $S$, $A = \{e, a\}$, $U = \{u\}$, $G = \{g\}$, $V = \{v\}$ and $B = \{b, f\}$ are archimedean classes and $A\delta = G\delta = B\delta$, $A\delta < U\delta$, $A\delta < V\delta$. Since $ab = u$, Lemma 9 does not hold in general without the assumption that $S$ is nonnegatively ordered. Also we have $ab^2 = g$ but neither $ab = u A g$ nor $b^2 = f A g$. Hence Lemma 13 does not hold in general without the assumption that $S$ is nonnegatively ordered.

4. In [7] Kožikašvili and Loginov proved that in an ordered semigroup $S$ which satisfies the conditions (1) for $x, y, z \in S$, $x < y$ implies $xz < yz$ and $xz < zy$, and (2) $xz > x$ and $zx > x$ for every $x, z \in S$ such that $z$ is not the identity of $S$, the subsemigroup generated by a well-ordered subset of $S$ is also a well-ordered subset of $S$. 
As an application of the preceding section, in this section we extend the result of ˇZoˇzikaˇšvili and Loginov for nonnegatively ordered semigroups. The proof is carried out in a similar way to that in [7].

In this section, we denote by $S$ a nonnegatively ordered semigroup.

**Lemma 18.** If $M_1$ and $M_2$ are well-ordered subsets of $S$, then the set product $M_1M_2$ is also a well-ordered subset of $S$.

**Proof.** By way of contradiction, we assume $M_1M_2$ is not well ordered. Then there exists an infinite sequence $x_1 > x_2 > x_3 > \ldots$ of elements of $M_1M_2$. Since $x_i \in M_1M_2$, we have $x_i = x_{i1}x_{i2}$ for some $x_{i1} \in M_1$ and $x_{i2} \in M_2$. Since $M_1$ is well-ordered, \{ $x_{i1}$ : $i = 1, 2, 3, \ldots$ \} has the least element $y_1$. We put $I_1 = \{ i : x_{i1} = y_1 \}$. By way of contradiction, we assume $I_1$ is infinite and consists of $i_1 < i_2 < i_3 < \ldots$. Then

$$x_{i1} = x_{i11}x_{i12} = y_1x_{i12} \succ x_{i2} = x_{i12}x_{i12} = y_1x_{i12}^2 \succ x_{i13} = x_{i12}x_{i13} = y_1x_{i13}^2 \succ \ldots,$$

whence we have an infinite sequence $x_{i11}^2 > x_{i12}^2 > x_{i13}^2 > \ldots$ of elements of $M_2$, which contradicts the fact that $M_2$ is well-ordered. Hence $I_1$ is finite and so we can take $n_1 = \max I_1$. Then if $i > n_1$, then $i \not\in I_1$ and so $x_{i1} > y_1$. Also we have $x_{n_1} > x_i$. Hence

$$y_1x_{n_12} = x_{n_1}x_{n_12} = x_{n_1} > x_i = x_{i1}x_{i2} \succeq y_1x_{i2}$$

and so $x_{n_12} > x_{i2}$. Thus we have shown that $x_{n_12} > x_{i2}$ for every $i > n_1$. 
Now suppose that $m$ is a natural number such that $x_{i12} > x_{i2}$ for every $i > m$. Since $M_1$ is well-ordered, $\{ x_{i1} : i \geq m + 1 \}$ has the least element $y_m$. We put

$$I_m = \{ i : i \geq m + 1 \text{ and } x_{i1} = y_m \}.$$ 

By way of contradiction, we assume $I_m$ is infinite and consists of elements $i_{m1} < i_{m2} < i_{m3} < \ldots$. Then

$$x_{i_{m1}} = x_{i_{m1}}^1 x_{i_{m1}}^2 = y_{m} x_{i_{m1}}^2 > x_{i_{m2}} = x_{i_{m2}}^1 x_{i_{m2}}^2 = y_{m} x_{i_{m2}}^2 > \ldots,$$

whence we have an infinite sequence $x_{i_{m1}}^2 > x_{i_{m2}}^2 > x_{i_{m3}}^2 > \ldots$ of elements of $M_2$, which contradicts the fact that $M_2$ is well-ordered. Hence $I_m$ is finite and so we can take $n_m = \max I_m$.

For $i > n_m$, we have $i \not\in I_m$ and also $i > n_m \geq m + 1$ and so and so $x_{i1} > y_m$. Also we have $x_{n_m} > x_i$. Hence

$$y_{m} x_{n_m}^2 = x_{n_m}^1 x_{n_m}^2 = x_{n_m} > x_i = x_{i1} x_{i2} = y_{m} x_{i2}$$

and so $x_{n_m}^2 > x_{i2}$. Also, since $n_m \geq m + 1 > m$, we have $x_{m2} > x_{n_m}^2$.

Thus we have shown that there exists a natural number $n_m$ such that $n_m > m$, $x_{m2} > x_{n_m}^2$ and $x_{n_m}^2 > x_{i2}$ for every $i > n_m$. Hence we obtain an infinite sequence $x_{n_1}^2 > x_{n_2}^2 > x_{n_3}^2 > \ldots$ of elements of $M_2$, which contradicts that $M_2$ is well-ordered. This proves that $M_1 M_2$ is well-ordered.

From Lemma 18, we have, by induction

**COROLLARY 19.** If $M_1, M_2, \ldots, M_k$ are well-ordered subsets of $S$, then $M_1 M_2 \ldots M_k$ is also a well-ordered subset of $S$.

**LEMMA 20.** Let $M$ be a well-ordered subset of $S$, let $L$ be the subsemigroup generated by $M$ and let $B$ be the set of all archimedean classes of the semigroup $L$. Then $B$ is a well-ordered set.
PROOF. Let $B'$ be a nonempty subset of $B$. Let $B \in B'$ and let $x \in B$. Then, since $x \in B \subseteq L$, there exists a finite number of elements $x_1, x_2, \ldots, x_n$ of $M$ such that $x = x_1x_2\ldots x_n$. By Corollary 16, there exists $y \in M \cup M^2$ such that $x \leq y$. Thus we have shown that each archimedean class $B$ in $B'$ contains a representative $x(B) \in M \cup M^2$. Then $X = \{ x(B) ; B \in B' \}$ is a nonempty subset of $M \cup M^2$. But $M \cup M^2$ is a well-ordered subset of $S$ by Lemma 18 and so there exists $B_0 \in B'$ such that $x(B_0) = \min X$. Then clearly $B_0$ is the least element of $B'$. This proves that $B$ is well-ordered.

**LEMMA 21.** Let $M$ be a well-ordered subset of $S$ and let $L$ be the subsemigroup generated by $M$. Then every archimedean class of the semigroup $L$ is a well-ordered subset of $S$.

**PROOF.** By way of contradiction, we assume that there exists an archimedean class of $L$ which is not well-ordered. Then, by Lemma 20, there exists the least archimedean class $X$ which is not well-ordered. As above we denote by $B$ the set of all archimedean classes of the semigroup $L$. Thus, if $Y \in B$ and $Y < X$, then $Y$ is well-ordered.

We put $U = \cup \{ Y \in B ; Y < X \}$.

(a) If $U \neq \emptyset$, then $U$ is a subsemigroup of $S$.

In fact, let $y, z \in U$. Then $y \in Y$ and $z \in Z$ for some $Y, Z \in B$ such that $Y < X$ and $Z < X$. If $y \leq z$, then $yz \leq z^2 \in Z$ and so $yz \in W$ for some $W \in B$ such that $W \leq Z < X$, whence $yz \in U$. If $z \leq y$, then we can obtain $yz \in U$ in a similar way.

Similarly we can prove

(b) $X \cup U$ is a subsemigroup of $S$.

(c) If $U \neq \emptyset$, then $U$ is a well-ordered subset of $S$.

In fact, let $V$ be a nonempty subset of $U$ and let
\[ B' = \{ B \in B ; B \cap V \neq \emptyset \}. \text{ Then } B' \text{ is a nonempty subset of } B. \]

Hence, by Lemma 20, we can take \( B_0 = \min B' \). Then \( B_0 \in B' \) and, by the definition of \( U \), \( B_0 < X \) and so, by assumption, \( B_0 \) is well-ordered. Hence we can take \( b_0 = \min (B_0 \cap V) \). Now it is clear that \( b_0 \) is the least element of \( V \).

Put \( T = M \cup UM \cup MU \cup UMU \cup M^2 \cup UM^2 \cup M^2U \cup UM^2U \).

(d) Every element \( x \in X \) can be written in the form \( x = t_1 t_2 \ldots t_m \) with \( t_1, t_2, \ldots, t_m \in T \cap X \).

In fact, let \( x \in X \). Then, since \( x \in X \subseteq L \), \( x = x_1 x_2 \ldots x_k \) for some \( x_1, x_2, \ldots, x_k \in M \). By Corollary 16, there exists \( y \in M \cup M^2 \) such that \( x \leq y \). Then \( y \in X \). Also, since \( S \) is nonnegatively ordered, there exists a natural number \( s \) such that \( x \leq y^s \). We denote by \( X_i \) the archimedean class containing the element \( x_i \). Suppose \( x < X_i \) for some \( i \). Then we have \( x \leq y^s < X_i \).

Putting \( p = x_1 \ldots x_{i-1} \) and \( q = x_{i+1} \ldots x_k \) (\( p \) or \( q \) may be the empty symbol), we have \( px_i q = x \leq y^s < X_i \). Since \( S \) is nonnegatively ordered, we have \( p \leq p^2 \) and \( q \leq q^2 \) and so \( px_i q \leq p^2x_i q^2 = pxq \leq py^s q \leq px_i q \).

Hence \( x = px_i q = py^s q \). Applying this procedure several times, we obtain an expression \( x = y_1 y_2 \ldots y_h \) with \( y_1, y_2, \ldots, y_h \in (M \cup M^2) \cap (X \cup U) \). Finally, by (a) and (b), we obtain an expression \( x = t_1 t_2 \ldots t_m \) with \( t_1, t_2, \ldots, t_m \in T \cap X \).

Now we return to the proof of the lemma. Since the archimedean class \( X \) of \( L \) is not well-ordered, there exists an infinite sequence \( z_1 < z_2 < z_3 < \ldots \) of elements of \( X \). Since \( X \) contains at most one idempotent and, if \( X \) contains an idempotent, then the idempotent is the greatest element of \( X \), we can assume that each one of \( z_1, z_2, z_3, \ldots \) is not an idempotent. Since \( U \) and \( M \) are well-ordered subsets of \( S \), it follows from Corollary 19 that \( T \) is
well-ordered. Hence $T \cap X$ contains the least element $t_0$. Then, since $z_1$ is not an idempotent and $z_1$ and $t_0$ are archimedean equivalent, there exists a natural number $k$ such that $z_1 < t_0^k$. By (d), for each $z_i$, there is a representation $z_i = t_1t_2\ldots t_m$ with $t_1, t_2, \ldots, t_m \in T \cap X$. If $k < m$ were true, then $t_0^{k+1} \leq t_0^m \leq t_1t_2\ldots t_m = z_i \leq z_1 < t_0^k$, which contradicts the fact that $S$ is nonnegatively ordered. Hence $m \leq k$ and so $z_i \in \bigcup_{j=1}^k T_j$. But, by Corollary 19, $T$ is well-ordered and so also $T_j$ is well-ordered for every $j$ such that $1 \leq j \leq k$. Hence $\bigcup_{j=1}^k T_j$ is a well-ordered subset of $S$ and also contains an infinite sequence $z_1 < z_2 < z_3 < \ldots$, which is a contradiction. This proves Lemma 21.

**Theorem 22.** In a nonnegatively ordered semigroup $S$, let $M$ be a well-ordered subset and let $L$ be the subsemigroup of $S$ generated by $M$. Then $L$ is also a well-ordered subset of $S$.

**Proof.** Suppose $\square \neq N \subseteq L$. We denote by $B$ the set of all archimedean classes of the semigroup $L$. We put $B' = \{ X \in B \mid X \cap N \neq \square \}$. Then, by Lemma 20, there exists $X_0 = \min B'$ and $X_0 \cap N \neq \square$. Also, by Lemma 21, there exists $x_0 = \min(X_0 \cap N)$. Then clearly $x_0$ is the least element of $N$. Hence $L$ is well-ordered.
