Supplement to 'Minimal class generated by open compact and perfect mappings'

By Keiô Nagami

Dept. Math., Ehime University

This is a supplementary note on my lecture[4] at Kyoto Symposium on Topological Spaces, Dec.2, 1971. A space is called a weak p-space if it is regular $(T_1 + T_3)$ and has a sequence $(0)_i$, $i=1,2,\cdots$, of open coverings of X satisfying: If $x \in U_i$ $\in U_i$, $i=1,2,\cdots$, then i) $\bigcap_{i=1}^{\infty} \overline{U_i}$ is compact and ii) $\bigcap_{i=1}^{\infty} \overline{U_i} \subset U$ with U open implies $\bigcap_{i=1}^{\infty} \overline{U_i} \subset \bigcap_{i=1}^{n} \overline{U_i} \subset U$ for some n. This sequence $\{ (\widehat{\mathbb{U}}_{i}) \}$ is called a <u>defining</u> one. This condition was introduced by Burke[2], Theorem 1.3, where he proved that a completely regular space is a p-space in the sense of Arhangel'skii[1], Definition 5, if and only if it is a weak p-space. However the space T in Engelking[3], Example 2.4.4, p.85, is not a p-space but a weak p-space, which proof is left to the reader. Since every Moore space is evidently a weak p-space, the class of weak p-spaces offers a class containing all p-spaces and all Moore spaces. The property to be a weak p-space is inherited under the operations taking ${\sf G}_{\hat{\lambda}}$ sets, closed sets, perfect preimages and countable products. The aim of this paper is to note that wherever 'p-spaces' are in [4] is replaced by 'weak p-spaces'. That can easily be verified with the aid of the following Lemmas 1 and 2 and

with trivial miner changes of the original proofs in [4]. For undefined terminologies refer to [4].

LEMMA 1. Let X be a weak p-space with a derining sequence $\{ \ \, \stackrel{\frown}{\mathbb{U}}_{\mathbf{i}} = \{ \ \, \mathbf{U}_{\mathbf{i}\alpha} \colon \alpha \in \mathbf{A}_{\mathbf{i}} \} \colon \mathbf{i}=1,2,\cdots \} \text{. Let } \mathbf{B}_{\mathbf{i}} \text{ be a finite subset}$ of $\mathbf{A}_{\mathbf{i}} \text{ and } \varphi_{\mathbf{i}}^{\mathbf{i}+1} \colon \mathbf{B}_{\mathbf{i}+1} \longrightarrow \mathbf{B}_{\mathbf{i}} \text{ a transformation such that } \varphi_{\mathbf{i}}^{\mathbf{i}+1}(\alpha)$ $= \beta \text{ implies } \overline{\mathbf{U}}_{\mathbf{i}+1,\alpha} \subset \mathbf{U}_{\mathbf{i}\beta} \text{ and such that } \langle \alpha_{\mathbf{i}} \rangle \in \text{inv lim } \{\mathbf{B}_{\mathbf{i}};$ $\varphi_{\mathbf{i}}^{\mathbf{i}+1} \} \text{ implies } \bigcap_{i=1}^{\infty} \mathbf{U}_{\mathbf{i}\alpha} \neq \emptyset \text{. Set}$ $\mathbf{U}_{\mathbf{i}} = \mathbf{U}_{\mathbf{i}\alpha} \colon \alpha \in \mathbf{B}_{\mathbf{i}} \} \text{, } \mathbf{K} = \mathbf{0} \mathbf{U}_{\mathbf{i}}.$

Then K is compact and $\{U_i\}$ forms a neighborhood base of K in X. Proof. It suffices to consider the case: $K \neq \emptyset$. Let $\widehat{\mathbb{F}}$ be a maximal filtre of subsets of K. Set

$$C_{i} = \{ \alpha \in B_{i} : U_{i\alpha} \cap K \in \mathbb{F} \}.$$

Then $C_i \neq \emptyset$ and $\{C_i\}$ forms an inverse subsystem of $\{B_i\}$. Pick an element $\{\alpha_i\}$ from inv lim C_i . Set

$$L = \bigcap_{i=1}^{\infty} U_{i\alpha_{i}}.$$

Then L is a non-empty compact set with L \subset K. Let F be an arbitrary element of $\widehat{\mathbb{F}}$. Assume $\widehat{\mathbb{F}} \cap L = \emptyset$. Then $\widehat{\mathbb{F}} \cap U_{j\alpha} = \emptyset$ for some j, a contradiction. Thus a point of L adheres $\widehat{\mathbb{F}}$, which proves that K is compact.

To prove $\{U_i\}$ forms a neignborhood base of K in X assume the contrary. Let U be an open set of X with K \subset U and with $U_i - U \neq \emptyset$ for any i. Set

$$D_{i} = \left\{ \alpha \in B_{i} : U_{i\alpha} - U \neq \emptyset \right\}.$$

Then $D_{i} \neq \emptyset$ and $\{D_{i}\}$ forms an inverse subsystem of $\{B_{i}\}$.

Pick an element $\langle \beta_i \rangle$ from inv lim D_i . Set

$$M = \bigcap_{i=1}^{\infty} U_{i\beta_{i}}.$$

Since M \subset K, then U $_{k\beta_k}$ \subset U for some k, a contradiction. The proof is finished.

LEMMA 2. A weak p-space X is of countable type.

Proof. Let Q be a non-empty compact set of X and $\{\bigcup_i^n\}$ a defining sequence of open coverings of X. Let $\bigcup_i^n = \{\bigcup_{i \alpha} : \alpha \in A_i^n\}$ be an open covering of X such that i) \bigcup_i^n refines \bigcup_i^n , ii) $\overline{\bigcup_{i+1}^n}$ refines \bigcup_i^n , and iii) all but a finite number of elements of \bigcup_i^n do not meet Q. Then $\{\bigcup_i^n\}$ is also a defining one. Let $\{P_i^{i+1}:A_{i+1}\longrightarrow A_i^n\}$ be a transformation such that $\{P_i^{i+1}:A_{i+1}\longrightarrow A_i^n\}$ be a transformation such that $\{P_i^{i+1}:A_{i+1}\longrightarrow A_i^n\}$ be a transformation such that $\{P_i^{i+1}:A_{i+1}\longrightarrow A_i^n\}$ be a transformation such that

Then $B_i \neq \emptyset$ and $\{B_i\}$ forms an inverse subsystem of $\{A_i; \varphi_i^{i+1}\}$. Since the condition of Lemma 1 is satisfied, K defined in Lemma 1 is a compact set of countable character. Since $Q \subseteq K$, X is of countable type and the proof is finished.
