**ABSTRACT**—A new opheliid polychaete, *Euzonus japonicus* sp. nov., is described. This species was collected from subtidal zones in Japanese coasts, while most *Euzonus* species inhabit intertidal sandy beaches. *E. japonicus* sp. nov. is morphologically most similar to another subtidal species, *E. flabelliferus* (Ziegelmeier, 1955) collected from northern Europe, but different from that in the form of branchiae. They share a unique characteristic on setiger 10, i.e., a pair of lateral transverse rows of conical cirri, instead of a pair of lateral smooth ridges that are common to all intertidal *Euzonus* species.

**Key words:** taxonomy, new species, Polychaeta, Opheliidae, subtidal habitat

**INTRODUCTION**

Most *Euzonus* species inhabit intertidal sandy beaches consisting of well-sorted, medium to fine sands (Okuda, 1934; McConnaughey and Fox, 1949; Dales, 1952; Probert, 1976; Kemp, 1988; Buzhinskaja, 1991; Jaramillo et al., 1993; Jaramillo, 1994; Hartmann-Schröder and Parker, 1995; Souza and Gianuca, 1995). However, *E. flabelliferus* was collected from subtidal zones in the North Sea and the White Sea (Ziegelmeier, 1955; Tzetlin, 1978; Hartmann-Schröder, 1996), and *E. profundus* was collected from an abyssal depth of 4008 m, southeast off the Cape Horn (Hartman, 1967). The subtidal species, *E. flabelliferus*, has a unique morphological characteristic on setiger 10, i.e., a pair of lateral transverse rows of conical cirri, while all intertidal species have a pair of lateral smooth ridges on setiger 10 instead of conical cirri.

In East Asia including the Far East Region of Russia (Annenkova, 1935; Uschakov, 1955), northern Japan (Okuda, 1934, 1936; Imajima and Hartman, 1964), and the Chinese coast of the Yellow Sea (Dejian and Ruping, 1988), three intertidal species of the genus *Euzonus*. *E. arcticus*, *E. ezoensis* and *E. dillonensis* have been recorded, but no subtidal species has been recorded. *Thoracophilus yasudai* described by Okuda (1934) from Japanese coast of the Sea of Japan was regarded as a junior synonym of *E. arcticus* by Imajima and Hartman (1964).

In the course of our examination of Japanese opheliid polychaetes, we found a species belonging to the genus *Euzonus* from subtidal habitats. This species is similar to *E. flabelliferus* in both the unique morphological characteristic on setiger 10 and the subtidal habitat, but different from that in the form of branchiae. In the present paper, we describe this species as new to science and as the second subtidal species of the genus *Euzonus*.

**MATERIALS AND METHODS**

Specimens were collected using a bottom sampler from subtidal sandy bottoms at four collection sites in Japan (Fig. 1). These worms were fixed in 10% formalin for more than 24 hr, rinsed in freshwater and transferred to 80% ethanol for preservation, except for specimens collected from off Yura Beach, Miyazu in 25 September 2001, which were fixed in 100% ethanol for future DNA analysis. For the preserved specimens, body length (BL) and body height (BH) at setigers 5 and 15 were measured. The characteristics of lat-
eral cirri and branchiae were examined basically on the left side of the body except for some injured specimens. Drawings were made with a camera lucida and pictures were taken with a digital camera. The type materials are deposited in the National Science Museum, Tokyo (NSMT), Coastal Branch of Natural History Museum and Institute, Chiba (CMNH), the Senckenberg Museum, Frankfurt/M. (SMF), Zoological Museum, University of Copenhagen (ZMUC), and the United States National Museum of Natural History and Institute, Chiba (CMNH), the Senckenberg Museum, Frankfurt/M. (SMF), Zoological Museum, University of Copenhagen (ZMUC), and the United States National Museum of Natural History (Smithsonian Institution), Washington, D. C. (USNM).

SYSTEMATICS
Family Opheliidae Malmgren, 1867
Genus Euzonus Grube, 1866
Euzonus japonicus sp. nov.
Figs. 2–3
Euzonus sp. 1: Nishi et al., 2001: 256.

Type material. Holotype (NSMT-Pol-H459, BL: 13 mm) and 4 paratypes (CMNH-ZW001939, SMF-13240, ZMUC, USNM-1014014, BL: 7–15 mm): subtidal sandy bottom, depth of 15 m, Oura Bay (34°39′N, 138°57′E), Shimoda, Izu Peninsula, Shizuoka Prefecture, 25 July 2001, coll. T. Kato. All materials complete.

Other material examined. Subtidal sandy bottom, depth of 11.5–16 m, off Yumigahama Beach (35°36′N, 38°53.8′E), Minami-izu, Izu Peninsula, Shizuoka Prefecture, 25 May 2000, coll. R. Ueshima, 7 specimens (BL: 11–16 mm). Subtidal sandy bottom, depth of 3–5 m, off Yura Beach (35°31′N, 135°17′E), Miyazu, Kyoto Prefecture, 20 August 1973, coll. I. Hayashi, 10 specimens (BL: 4–11 mm); 25 September 2001, coll. T. Misaka, 7 specimens (BL: 8–18 mm). Subtidal fringe of intertidal sandflat, Tomioka Bay (32°31′N, 130°02′E), Reihoku, Amakusa-Shimoshima Island, Kumamoto Prefecture, 14 June 1999, coll. A. Tamaki, 6 specimens (BL: 8–11 mm). All materials complete.

Description of the holotype. Body fusiform, divided into three distinct regions: cephalic region consisting of small pointed prostomium and 2 setigers; inflated thoracic region consisting of 8 setigers, separated from cephalic region by constriction behind setiger 2; abdominal region consisting of 22 setigers and pygidium, separated from thoracic region by swollen setiger 10; total of 32 setigers (Figs. 2a and 3a). Longitudinal midventral groove present, shallow in thoracic region, deep in abdominal region; pair of longitudinal lateral grooves present in abdominal region. Pair of dorsolateral nuchal grooves present in cephalic region. Ventral mouth slit present in cephalic region, proboscis eversible. Prostomial eyes absent.

Pair of lateral transverse rows of 11 dorsal and 3 ventral conical cirri present on setiger 10 (last thoracic setiger) (Figs. 2b and 3c). Ventral conical cirri present on setigers 9 to 25: 3 cirri on setigers 9 to 12, 2 cirri on setigers 13 to 15, and single cirrus on setigers 16 to 25, decreasing gradually to posterior setigers in size.

15 pairs of branchiae present, occurring on setigers 12 to 26 (Figs. 2a, c and 3a, b, e); branchiae palmatifid with 4–7 finger-shaped branches.

Parapodia biramous, minute. Segmental eyes absent. Notosetae and neurosetae all simple capillary setae, arising from slightly posterior to each parapodial lobe. Notosetae longer than neurosetae at all setigers, except for last 6 setigers (setigers 27 to 32) where notosetae and neurosetae equal in length. Setae on setigers 2 to around 5 and setigers 27 to 31 markedly longer than setae on other setigers.

Last 5 setigers (setigers 28 to 32) decreasing rapidly to pygidium in size (Fig. 3b). Pygidium consisting of two lateral lobes, lacking triangular midventral anal plate; each lateral lobe fringed with 12 minute tapering cirri; midventral anal cirrus obscure (Fig. 3g).

Allometry and variation. All 35 specimens collected from four localities were pooled for the analysis of allometry and variation. Body height (BH mm for setiger 1, BH2 mm for setiger 15) was correlated with body length (BL mm) according to the regression formulae (Fig. 4): BH1 = 0.08 BL + 0.6 ($r^2 = 0.64$, $P<0.0001$), BH2 = 0.1 BL + 0.2 ($r^2 = 0.67$, $P<0.0001$). Maximum body length was 18 mm. Total number of setigers was 31 or 32 possibly, though its exact count

---

New species of *Euzonus* from Japan

was difficult because the last 2–3 setigers were often immersed into an anterior one owing to various extent of constriction by fixation.

The number of dorsal and ventral conical cirri on setiger 10 varied between 6 and 11 (average±SD: 9.2±1.4) and between 2 and 4 (2.5±0.6), respectively. The number of dorsal conical cirri (D) was correlated with body length according to the regression formula (Fig. 5a): D=0.18 BL+7.2 (r²=0.25, P=0.002). The number of ventral conical cirri on setiger 10 was almost constant at 2 or 3, and not significantly correlated with body length (r=0.18, P=0.3) (Fig. 5b). The first setiger with ventral conical cirri was setiger 9 constantly, but the last setiger with those varied between setiger 17 and setiger 25. Therefore, number of setigers with ventral cirri (VC) varied between 9 and 17 (14.7±2.1), and it was correlated with body length according to the regression formula (Fig. 5c): VC=0.25 BL+12 (r²=0.22, P=0.004).

All the specimens had 15 pairs of branchiae occurring on setigers 12 to 26 without any variation in their arrangement. The maximum number of branches of a branchia (B)
varied between 3 and 7 (5.3 ± 1.0), and it was correlated with body length according to the regression formula (Fig. 5d):
\[ B = 0.19 \times BL + 3.3 \] 
\[ (r^2 = 0.49, P < 0.0001) \]. The branchiae were well-stretched in some specimens (Figs. 2c and 3e), while relatively shrunk in other ones (Fig. 3f), probably owing to various extent of constriction by fixation.

Fig. 3.  *Euzonus japonicus* sp. nov.  a–c, e, g: Holotype (NSMT-Pol-H459).  d: Nontype collected from off Yura Beach, Miyazu in 25 September 2001.  f: Paratype (CMNH-ZW001939).  h: Nontype collected from off Yumigahama Beach, Minami-izu in 25 May 2000.  a: Whole body, lateral view.  b: Posterior end, lateral view.  c: Lateral transverse row of dorsal conical cirri (DCC) on setiger 10.  d: Lateral transverse row of dorsal conical cirri (DCC) on setiger 10 and ventral conical cirri (VCC) from setiger 9.  e: Branchiae, well-stretched, and ventral conical cirri (VCC) on the middle abdominal region.  f: Branchiae, relatively shrunk, and ventral conical cirri (VCC) on the middle abdominal region.  g: Posterior end, ventral view. The midventral anal cirrus is invisible.  h: Posterior end, ventral view. The midventral anal cirrus is visible (VAC).
The number of cirri on each lateral lobe of pygidium varies between 7 and 12, though exact count was difficult because of the minute size of the cirri. Midventral anal cirrus was often obscure, but visible as a tiny round protrusion between the two lateral lobes at least in some specimens (Fig. 3h).

Reproduction. Oocytes (70–80 µm in diameter) were contained in the body cavity of 5 females: 3 specimens (BL: 11–14 mm) collected from off Yumigahama Beach, Minamiizu in 25 May 2000 and 2 specimens (BL: 16–17 mm) collected from off Yura Beach, Miyazu in 25 September 2001.

Habitat. Subtidal sandy bottoms.

Distribution. Japanese coasts of the Pacific Ocean, the Sea of Japan and the East China Sea (Fig. 1).

Etymology. The specific name refers to Japan, the type locality of this species.

Remarks. *Euzonus japonicus* sp. nov. is morphologically most similar to *E. flabelliferus* (Ziegelmeier, 1955) known in northern Europe (the North Sea and the White Sea); they share a unique characteristic on setiger 10, i.e., a pair of lateral transverse rows of conical cirri, instead of a pair of lateral smooth ridges that is common to most *Euzo-

E. japonicus sp. nov. differs from E. flabelliferus in some characteristics (Table 1): E. japonicus sp. nov. has palmatifid branchiae with 3–7 finger-shaped branches, while E. flabelliferus has tridil, bifid or unbranched branchiae (Ziegelmeier, 1955). In comparison using individuals with corresponding BL of 3.8–9.0 mm (values for E. flabelliferus are based on data shown in Ziegelmeier, 1955), maximum number of branches in a branchia was significantly larger in E. japonicus sp. nov. (6–10, 8.5±0.7, n=22) than in E. flabelliferus (5–7, 6.2±0.7, n=22) (P<0.0001) (Fig. 5a). Number of ventral conical cirri on setiger 10 was significantly larger in E. japonicus sp. nov. (6–11, 8.5±0.9, n=14) than in E. flabelliferus (5–7, 6.2±1.4, n=14) (P<0.0001) (Fig. 5d). Number of dorsal conical cirri on setiger 10 was significantly larger in E. japonicus sp. nov. (6–10, 8.5±1.4, n=14) than in E. flabelliferus (5–7, 6.2±0.7, n=22) (P<0.0001) (Fig. 5a). Number of ventral conical cirri on setiger 10 was significantly larger in E. japonicus sp. nov. (6–10, 8.5±1.4, n=14) than in E. flabelliferus (5–7, 6.2±0.7, n=22) (P<0.0001) (Fig. 5a).

We re-examined ten specimens, which were collected from off Yura Beach, Miyazu in 20 August 1973 and reported as E. ezoensis by Yokoyama and Hayashi (1980), and judged them as E. japonicus sp. nov. Horikoshi and Tamaki (1978) and Sakurai et al. (2001) also reported the occurrence of “E. ezoensis” from subtidal zones up to 19 m in depth in northern Japan. Their specimens also may be E. japonicus sp. nov. though we have not examined them.

ACKNOWLEDGEMENTS

We are grateful to Isao Hayashi (Kyoto University), Tetsuya Kato (Hokkaido University), Rel Ueshima (University of Tokyo) and Akio Tamaki (Nagasaki University) for kindly providing materials, and Masahiro Ueno (Kyoto University), staff of Fisheries Research Station of Kyoto University and staff of Shimoda Marine Research Center of University of Tsukuba for their help in collection of materials. We also thank Alexander Tzetlin (State University of Moscow) and Mary E. Petersen (Zoological Museum, Copenhagen) for their help with literature information, and two referees for their helpful comments.
