A CASE OF PRIMARY URETHRAL LYMPHOMA PRESENTING AS A HUGE MASS SURROUNDING THE FEMALE URETHRA

Yousuke Shimizu, Osamu Ogawa, Toshiro Terachi, Yusaku Okada and Osamu Yoshida

From the Department of Urology, Faculty of Medicine, Kyoto University

A patient with a primary malignant lymphoma surrounding the female urethra is reported. Despite the good response of the primary tumor to radiotherapy, the patient died shortly after diagnosis due to disseminated disease. We reviewed 16 cases of this rare entity reported previously.

Key words: Female urethra, Malignant lymphoma, Radiotherapy

INTRODUCTION

Malignant lymphoma can affect almost any organ of the body, although it usually originates in the lymph nodes. The incidence of malignant lymphomas in urogenital organs is low. Limited clinical experience has resulted in uncertainty concerning the most appropriate form of therapy for this malignancy. We report an 82-year-old woman with non-Hodgkin’s lymphoma presenting as a huge tumor surrounding the female urethra.

CASE REPORT

An 82-year-old woman consulted our hospital with complaints of dysuria and sense of residual urine which had persisted for 2 months. Physical examination revealed an elastic hard mass along the urethra. Laboratory examination revealed no abnormal findings except the elevation of serum level of lactic dehydrogenase (555 IU/L; normal <230). Cystoscopy revealed the bladder neck elevated by the mass around the urethra, although the bladder mucosa was smooth, indicating that the tumor had originated from the paraurethral region. Gynecological examination did not reveal any abnormal findings in female genital organs. Pelvic computed tomography (CT) and magnetic resonance imaging (MRI) revealed a 5.5 cm x 5 cm x 5.2 cm mass surrounding the urethra (Fig. 1). Cold cup biopsy was performed, and the histopathological examination showed infiltration of poorly differentiated malignant cells (Fig. 2). After immunohistochemical staining of the specimen (CD20 (+), CD45RO (-), CD3 (-), CD15 (-), CD68 (-)), the tumor was diagnosed as non-Hodgkin’s lymphoma, B cell type, diffuse and large cell type according to the Lymphoma Study Group in Japan (LSG) classification

Fig. 1. MRI revealed a large homogeneous mass (5.5 cm x 5 cm x 5.2 cm) surrounding the urethra.

Fig. 2. Histological examination of the biopsy specimen revealed proliferation of small and large malignant cells that were diagnosed as lymphoma cells by immunohistochemical analysis.
bone marrow aspiration biopsy failed to show the infiltration of lymphoma cells. Under the diagnosis of locally invasive urethral malignant lymphoma, the patient underwent 40 Gy radiotherapy to the whole pelvis and the bilateral inguinal region. Although the primary lesion responded well to the radiotherapy (Fig. 3), multiple lung metastases appeared during the therapy. The patient died of disseminated disease five months after radiotherapy despite oral administration of 25 mg/day of etoposide.

**DISCUSSION**

According to Freeman's study\(^2\), primary urogenital malignant lymphomas are relatively rare, and comprised 2.6% of all extranodal lymphomas. To the best of our knowledge, only 16 cases of urethral lymphoma, including 2 male patients, have been reported, all being histopathologically diagnosed as non-Hodgkin lymphomas (Table 1). Urethral lymphomas usually present with a painless mass resembling a caruncle. This patient, however, had a huge mass beneath the bladder neck indicating infiltration to the periurethral tissue. This particular pattern of tumor growth was the cause of her major complaint of dysuria with a sense of residual urine.

There is no consensus about treatment of urethral lymphoma. Various treatments have been applied to urethral lymphoma. Of the 16 patients reported previously 12 had no evidence of disease at 31.7 months of mean follow-up. Although the number of patients was very small and the follow-up period was short in all cases, local therapy including excision or external beam radiation with/without chemotherapy showed a good outcome in patients with local or locally invasive tumor. However, patients with disseminated disease showed a poor prognosis regardless of the kind of initial treatment. The

[16] and [17] are males. NED=No evidence of disease
present patient died only seven months after diagnosis despite a good response of the primary tumor to external radiotherapy. According to the Rappaport grading system or the Working Formulation, diffuse histology and high grade tumor are considered to show a more unfavorable outcome than nodular subtype and intermediate grade tumors. In patients with these types of unfavorable histology or disseminated disease, early intensive chemotherapy is recommended.
