From the Department of Urology, Osaka City University Medical School

Tetsuo KUROKI

From the Division of Hematology, Osaka City University Medical School

A clinical study was made on the relationship between the blood type P₁ antigen and urinary tract infection (UTI).

The blood type P₁ antigen could be detected in 3 out of 11 healthy Japanese volunteers (27.2%), and in 54% of the UTI patients as a whole. Classified by the type of infection, it could be detected in 3 out of 4 patients with upper UTI (75%) and in 11 out of 22 patients with lower UTI (50%). These incidences were higher than that of healthy volunteers, the difference being statistically significant.

The relationship between the annual frequency of UTI and the positive detection of P₁ antigen was examined. The patients who had been exposed to UTI twice or more a year proved to have a higher detection rate (61%), than the other group of patients, the difference being statistically significant.

Two of the patients with E. coli detected as a clinical isolate proved to have the P₁ antigen.

Key words: Urinary tract infection, Blood P₁ antigen

INTRODUCTION

Since the blood type P₁ antigen was detected by Landsteiner in 1927, this blood type has been known to have some connection with certain illnesses such as habitual abortion¹² and parasitic infection¹⁵. In recent years its connection with urinary tract infections (UTI) has also been suggested. We thus made a study on the relation of the blood type P₁ antigen with cases of UTI that we often encounter in our daily practice.

PATIENTS AND METHODS

The study involved 26 patients (4 males and 22 females) who visited the Urological Department of Osaka City University Hospital and its related hospitals. Five healthy male and 6 healthy female volunteers were also included in the study as a control group. (Table 1)

UTI: Urinary Tract Infection.

Anti-P₁ serum (Ortho) was used for detection of the blood type P₁ antigen, and P₁ antigen was judged as positive or negative on the basis of positive or negative hemagglutination of red blood cells (Fig. 1).
RESULTS

1. The positive rate of P₁ antigen in healthy volunteers (Table 2)
   P₁ antigen could be observed in 3 of the 11 volunteers (27.2%).

UTI: Urinary Tract Infection

2. The positive rate of P₁ antigen in the group of UTI
   Table 2 shows the positive rate of P₁ antigen in the 26 patients belonging to the group of UTI. As a whole, it was positive in 54%. If classified by the type of infection, it was positive in 3 out of 4 patients with upper UTI (75%) and in 11 out of 22 patients with lower UTI (50%), and the incidences were significantly higher than that in healthy volunteers (P<0.01).

3. The annual frequency of UTI and the positive rate of P₁ antigen (Table 3).
   The relationship between the annual frequency of UTI and the positive rate was next examined. The positive rate of P₁ antigen was significantly higher in patients who had suffered from UTI twice or more a year than the other patients (P<0.05).

4. The clinical isolates of bacteria and the positive rate of P₁ antigen (Table 4).
   The clinical isolates that could be identified were five kinds. The most common pathogen was E. coli which was isolated in 7 patients, followed by Proteus, Klebsiella, Serratia, and Pseudomonas which were detected in 1 patient each. Among these patients, P₁ antigen was found positive in only 2 of the patients with E. coli.

DISCUSSION

As mentioned above, the blood type P₁ antigen is supposed to be connected with various illnesses. Its relation with urinary...
Yasumoto et al.: UTI and Blood P₁ antigen

tract infections, among others, was first
described by Lomberg² in 1981, and later
similar results were reported by Roland³).
The results of our study seem to support
Lomberg's view that people having the
blood type P₁ antigen are more vulnera-
tible to urinary tract infections.

On the other hand, there is no definite
theory yet about where bacteria begins to
adhere to epithelial cells of the urinary
tract as the first step in inducing a uri-
nary tract infection. Roland, who noticed
the similarity between the glycolipid com-
position and the blood type P₁ antigen on
the bacterial surface, hypothesized that
adhesion of bacteria might begin in that
structure.
