Abstract

Although novel agents effective against malignant mesothelioma (MM) have been developed, the prognosis of patients with MM is still poor. We generated a DNA-chimeric siRNA against polo-like kinase-1 (PLK-1), which was more stable in human serum than the non-chimeric siRNA. The chimeric PLK-1 siRNA inhibited MM cell proliferation through the induction of apoptosis. Next, we investigated the effects of zoledronic acid (ZOL) on MM cells, and found that ZOL also induced apoptosis in MM cells. Furthermore, ZOL augmented the inhibitory effects of the PLK-1 siRNA. In conclusion, combining a PLK-1 siRNA with ZOL treatment is an attractive strategy against MM.

Key Words: PLK-1; RNA interference; DNA-chimeric siRNA; Bisphosphonate; Malignant mesothelioma
1. Introduction

Malignant mesothelioma (MM) is an aggressive tumor, which develops from the mesothelial surface of the pleural and peritoneal cavities. Asbestos is well-known as a carcinogen in MM and the incidence of MM is increasing worldwide [1]. Although several surgical approaches have been proven to be effective [2,3], a combination of therapies including chemotherapeutic agents, radiation, and immunotherapy are required to fight the disease. However, in spite of the emergence of novel effective anticancer agents such as pemetrexed [4,5] and raltitrexed [6,7], the prognosis of patients with MM is still poor [8,9]. Therefore, the development of novel effective therapeutic strategies is essential to improve the prognosis of this disease.

RNA interference (RNAi) is a process involving sequence specific post-transcriptional gene silencing induced by double-stranded (ds) RNA. It is widely applied as a powerful tool in postgenomic research, and has been experimentally introduced into the field of cancer therapy. Synthetic, short interfering RNAs (siRNAs) for inducing RNAi are 19- to 21- nucleotide dsRNAs with two-nucleotide 3’ overhangs at either end [10,11]. Unfortunately, siRNAs are degraded by endogenous nucleases when administered in vivo. Many techniques, including the use of DNA-chimeric siRNAs, have been developed to protect siRNAs from such degradation [10,12,13].
Previous investigations have revealed that their silencing activity is as powerful as that of non-chimeric siRNAs [12-14].

Polo-like kinase-1 (PLK-1) belongs to the PLK family of serine/threonine kinases and is highly conserved among eukaryotes. PLK-1 regulates cell division at several points during the mitotic phase of the cell cycle, including: mitotic entry through CDK1 activation, bipolar spindle formation, chromosome alignment, segregation of chromosomes, and cytokinesis [15,16]. Previous studies have reported that PLK-1 is overexpressed in cancerous tissues and that PLK-1 expression levels are tightly correlated with histological grades of tumors, clinical stages, and the patients’ prognosis [17-20]. Thus, PLK-1 is considered to be a suitable target for cancer therapy, and several small molecular targeting agents have been used in clinical trials [21,22], while siRNAs against PLK-1 have been investigated in preclinical studies [19,20,23].

Bisphosphonates (BPs) are inhibitors of bone-resorption, and second- and third- generation BPs have been developed primarily to treat benign and malignant bone disease [24]. This class of drugs inhibits the proliferation of cancer cells by preventing the post-translational prenylation of small GTPases including the Ras family proteins [25]. We have demonstrated previously that third-generation BPs such as zoledronic acid (ZOL) and minodronic acid (YM529) have direct anti-tumor effects.
against different cancer cells [26-30].

In the present study, we have investigated the effects of a DNA-chimeric PLK-1 siRNA and ZOL on MM cells \textit{in vitro}. Our results show that these agents induce apoptosis and inhibit the proliferation of MM cells. In addition, we found that ZOL enhances the inhibitory effects of the PLK-1 siRNA.

2. Materials and Methods

2.1. Cell lines, reagents, and animals

The human MM cell lines H2452, H2052, H28, and 211H were cultured in RPMI1640 medium (Gibco, Tokyo, Japan) containing 10% heat-inactivated fetal calf serum (FCS; Invitrogen, Tokyo, Japan), \textit{l}-glutamine (Gibco), and 1% penicillin-streptomycin (Gibco). The normal human dermal fibroblast (NHDF) cells were cultured in Dulbecco’s Modified Eagle medium (DMEM; Gibco) containing 10% FCS, \textit{l}-glutamine, and 1% penicillin-streptomycin. All cell lines were maintained at 37°C in a fully humidified atmosphere of 5% CO\textsubscript{2} in air. All four MM cell lines were obtained from the American Type Culture Collection (Rockville, MD). Normal fibroblast NHDF cells were purchased from Kurabo (Osaka, Japan). LIC™ Transfection Reagent (Hayashi Kasei, Tokyo, Japan) was used for transfection into
MM cells. ZOL (1-hydroxy-2-[1H-imidazole-1-yl]ethylidene-bisphosphonic acid) was obtained from Novalits Pharma AG (Basel, Switzerland).

We generated two types of siRNA against PLK-1 (GenBank accession number NM_005030) using siDIRECT™ (alphaGEN Co, Ltd, Tokyo, Japan). One of the siRNAs contained of ribonucleotides and the other was a DNA-chimeric siRNA consisting partially of deoxyribonucleotides. The oligonucleotide sequences of the non-chimeric PLK-1 siRNA against PLK-1 were: sense strands, 5’-GCACCGAAACCGAGUUAAUCA-3’ and that antisense strand, 5’-AAUAACUCGUUUCGUGCAGCAG-3’. The sequences of the DNA-chimeric siRNA against PLK-1 were: sense strand, 5’-GCACCGAAACCGAg ttattca-3’, and antisense strand, 5’-aataacUCGGUUUCGGUGCAGCAG-3’. This DNA-modified siRNA was constructed by substituting six ribonucleotides at the 5’ end of the guide strand and the 3’ end of the passenger strand with the cognate deoxyribonucleotides (designated in lower case). The oligonucleotide sequences for the chimeric siRNA controls were: sense strand, 5’-GUACCGCACGUCAUUCGUAU-3’, and antisense strand, 5’-tacgaaUGACGUGCGUACGU-3’. The sequences for the non-chimeric control siRNA were: sense strand, 5’-GUACCGCACGUCAUUCGUAAUU-3’, and antisense strand, 5’- UACGAAUGACGUGCGUACGU-3’. All siRNAs used were chemically
synthesized (Hokkaido System Science Co. Ltd, Hokkaido, Japan).

2.2. Stability of the DNA-chimera siRNA in human serum

We investigated the stability of the DNA-chimeric and non-chimeric siRNAs in human serum. Each siRNA was incubated in human serum (95%) at 37°C. Serum RNase was inactivated by adding SDS and proteinase K, and then digested samples were loaded onto 15% polyacrylamide gel, which was then stained using SYBR Gold (Invitrogen).

2.3. Growth inhibitory effects of PLK-1 siRNA

Cell proliferation was determined by the modified MTT assay using the Cell-Counting Kit-8 (Dojindo Laboratory, Kumamoto, Japan) as previously described [19; 20]. Cells were seeded in a flat-bottomed 96-well plate (Becton Dickinson, Tokyo, Japan) at 3 x 10³ cells in 100μl of medium per well and incubated with serial dilutions of the DNA-chimeric siRNA for 72 hours. The mean of four samples was calculated. Half-maximal inhibition constants (IC₅₀) were determined with the nonlinear regression program CalcuSyn (Biosoft, Cambridge, UK).
2.4. Growth inhibitory effects of Zoledronic acid

Cell proliferation was determined by the modified MTT assay using the Cell-Counting Kit-8 as mentioned above. Cells were seeded in a flat-bottomed 96-well plate (Becton Dickinson, Tokyo, Japan) at $3 \times 10^3$ cells in 100$\mu$l of medium per well and incubated with serial dilutions of ZOL for 72 hours. The mean of four samples was calculated. Half-maximal inhibition constants (IC$_{50}$s) were determined with the nonlinear regression program CalcuSyn. We also evaluated the combined effects of concurrent PLK-1 siRNA and ZOL treatment on H2452 and H28 mesothelioma cell lines and the analyzed data is shown by the combination index (CI). CI is a method for quantifying drug cytotoxic synergism based on the mass-action law principle derived from enzyme kinetic models. This method was developed by Chou and Talalay [31,32] which has been widely used to evaluate interactions of antineoplastic agents [33-36].

Cells were incubated for 72 hours with six concentrations (0.25, 0.5, 0.75, 1.0, 1.5, or 2.0 times the IC$_{50}$) of each agent or both in combination using the constant ratio design followed by the modified MTT assay. We calculated the combination indexes (CIs) as reported previously [33-36], and calculated the fraction affected (Fa) at each dilution (for example, Fa of 0.25 equals 75% viable cells). This method provides a quantification of the synergism (CI < 1), additive effect (CI = 1), and antagonism (CI >
1) at different dose and effect levels [31]. Calculations of the CI were made under the assumption that the mechanisms of action of the evaluated drugs were not mutually exclusive.

2.5. Cell cycle and apoptosis analysis

Cell cycle analysis using propidium iodide (PI) was performed as previously described [20]. Apoptosis induced by each siRNA treatment or ZOL treatment was determined using the Annexin-V-FITC Apoptosis Detection Kit I (BD Pharmingen, San Jose, CA) as recommended by the manufacturer. Cells were analyzed with FACS CANTO II using Diva software (BD Bioscience).

2.6. Western blotting analysis

Following the transfection of cells with PLK-1 siRNA, or treatment with ZOL, as described above, the medium was aspirated and the cells were washed with ice-cold PBS (-). The cells were lysed with ice-cold RIPA buffer (50 mM Tris-HCl [pH 7.4], 0.25 M NaCl, 5 mM EDTA, 20 mM NaF, 1% NP-40) with PMSF (1 mM) and protease inhibitor (10 μg/ml). The cells were then scraped off the plate, and the suspension of cells in lysis buffer was transferred to a centrifuge tube, which was placed on ice for 15
minutes with an occasional vortex to ensure complete lysis. The cell suspension was then cleared by centrifugation at 14,000g for 30 minutes at 4°C, and the supernatant (total cell lysis) was either used immediately or stored at -80°C. The protein concentration was determined using the DC Protein Assay (Bio-Rad Laboratories, Osaka, Japan).

Immunoblotting was performed as previously described [20]. The following primary antibodies (Abs) were used: rabbit polyclonal anti-PLK-1 Ab (Upstate Biotechnology Inc., Charlottesville, VA); rabbit polyclonal anti-caspase-3 Ab; rabbit polyclonal anti-cleaved caspase-3 Ab (Cell Signaling Technology, Danvers, MA); polyclonal anti-Rap1A Ab (Santa Cruz Biotechnology, Santa Cruz, CA); mouse monoclonal anti-RhoA Ab (Santa Cruz Biotechnology); mouse monoclonal anti-Ras Ab (BD Bioscience), and rabbit polyclonal anti-actin Ab (Sigma-Aldrich, Tokyo, Japan).

3. Results

3.1. Stability of the DNA-chimera siRNA in human serum

An siRNA can be protected from RNase or nuclease cleavage by the partial substitution of ribonucleotides with deoxyribonucleotides at the 5’ end of the guide
strand and the 3’ end of the passenger strand. Therefore, we first designed the PLK-1 siRNA using siDIRECT™ and then converted this siRNA into a DNA-chimeric siRNA. We incubated the DNA-chimeric, or non-chimeric siRNAs against PLK-1 in 95% human serum and investigated their degeneration. The non-chimeric siRNA degenerated in a time-dependent manner, while the DNA-chimeric siRNA did not degenerate for at least 120 minutes (Fig. 1A). This result shows that the chimeric siRNA is more stable in human serum than the non-chimeric siRNA.

3.2. DNA-chimeric PLK-1 siRNA inhibited the growth of mesothelioma cells

We examined the PLK-1 expression in four MM cell lines: H2452, H2042, H28, and 211H cell lines. All cell lines examined expressed a higher level of PLK-1 than normal NHDF fibroblast cells (Fig. 1B). Next we confirmed the knockdown effects of both DNA-chimeric and non-chimeric PLK-1 siRNAs in MM cells. We transfected both types of siRNAs into H2452 MM cells, and both siRNAs effectively knocked down PLK-1 expression (Fig. 1C). Then we investigated the inhibitory effects of the DNA-chimeric PLK-1 siRNA on MM cells in vitro. Western blot analysis showed that the transfection of the DNA-chimeric PLK-1 siRNA suppressed PLK-1 expression in H2452 mesothelioma cells in a dose-dependent manner, whereas the
nonsense chimeric siRNA (100 nM) did not (Fig. 2A). The IC\textsubscript{50} values for H2452 and H28 cells at 72 hours exposure were 1.6 nM and 38.7 nM, respectively. Our next step was to examine the growth inhibitory effects of the DNA-chimeric siRNA against PLK-1 on H2452 and H28 mesothelioma cells using a modified MTT assay. As shown in Fig. 2B, the chimeric PLK-1 siRNA inhibited cell growth in a dose-dependent manner, whereas no significant inhibitory effects were detected in normal NHDF cells (Fig. 2C).

3.3. The mechanisms of cell death induced by PLK-1 depletion

Next we investigated the mechanisms of cell death caused by PLK-1 siRNA transfection. Cell cycle analysis confirmed that PLK-1 siRNA treatment induced G2/M arrest as previously reported [19,20], and revealed an increase in the subG1 fraction 72 hours after transfection with the DNA-chimeric PLK-1 siRNA (Fig. 3A, upper panel). Early apoptotic cells (Annexin-V+/PI- fraction), and late apoptotic cells and necrotic cells (Annexin-V+/PI+ fraction) also increased after DNA-chimeric PLK-1 siRNA transfection (Fig. 3A, lower panel). In addition, Western blotting analysis demonstrated an increase in cleaved caspase-3 activity following PLK-1 siRNA transfection (Fig. 3B). Thus, transfection with a PLK-1 siRNA transfection resulted in the induction of
apoptosis in mesothelioma cells through the activation of caspase-3.

3.4. ZOL inhibits the growth of mesothelioma cells and synergistically augments with the effects of the PLK-1 siRNA

We examined the inhibitory effects of ZOL on H2452 and H28 mesothelioma cells using a modified MTT assay. ZOL inhibited cell growth in a dose-dependent manner, and the IC₅₀ values for H2452 and H28 cells at 72 hours exposures were 11.4 μM and 58.1 μM, respectively (Fig. 4A). ZOL treatment increased the subG1 fractions (Fig. 4B) and the number of apoptotic cells (Fig. 4C) in a dose-dependent manner. Furthermore, we found that caspase-3 was cleaved by ZOL treatment (Fig. 5A).

Next we investigated the unprenylation of Rap1A, RhoA, and Ras proteins. MM cell lysates were analyzed by Western blotting using Abs against Ras and the unprenylated form of Rap1A and RhoA. ZOL treatment resulted in an increase in unprenylated Rap1A and RhoA in MM cells (Fig. 5B). The anti-Ras Ab recognizes both a slower migrating band, representing the unprenylated Ras, and a faster migrating band representing the prenylated Ras [37]. After ZOL treatment, there was an increase in the unprenylated form of Ras in MM cells which was accompanied by a reduction in the prenylated form (Fig. 5B). Taken together, the results indicate that
ZOL treatment induced apoptosis through the cleavage of caspase by blocking the prenylation of small GTP-binding proteins, which resulted in the inhibition of cell growth of MM cells.

We then investigated the combined effects of ZOL treatment with the PLK-1 siRNA on H2452 and H28 MM cells. PLK-1 regulates RhoA in the mitotic phase [38,39]. The modified MTT assay with six concentrations (0.25, 0.5, 0.75, 1.0, 1.5, or 2.0 times the IC₅₀) of each agent or both in combination with the constant ratio was carried out. The values of the IC₅₀ which were obtained from the experiments above were used. We calculated the CIs and the Fa values at each dilution using the CalcuSyn soft as reported previously [33-36]. Dose-effect and CI-Fa plots illustrating the effects of PLK-1 siRNA and ZOL combinations are shown in Figure 5C. As shown in the left panel of Figure 5C, the treatment of PLK-1 siRNA combined with ZOL produced more growth inhibition than the treatments of each agent alone that are shown in Figures 2B and 4A. The mathematically analyzed data of CI-Fa plots are shown in the right panel of Figure 5C. In H2452 cells, the CI values at Fa 0.5, and 0.8 were 0.809 and 0.974, respectively; and in H28 cells, the CI values at Fa 0.5, and 0.8 were 0.082 and 0.836, respectively. These observations indicate that exposure to ZOL and the DNA-chimeric PLK-1 siRNA produced a synergistic effect on H2452 and H28 MM cell lines. We also
investigated the alternation of the unprenylated RhoA expression in H2452 and H28 cells by the treatment of PLK-1 siRNA and ZOL. The combined treatment of concurrent PLK-1 siRNA and ZOL did not alter the unprenylated RhoA expression compared to the treatment of ZOL alone (Supplementary Figure 1), suggesting that PLK-1 siRNA does not act on the prenylation of RhoA GTPase although PLK-1 siRNA diminishes PLK-1 expression.

Discussion

Synthetic siRNAs form complexes with liposomes, after which, the siRNA/liposome complex binds to the cell membrane and enters the cytoplasm via endocytosis. The complex then escapes from the endosome and releases its siRNA to the RNAi machinery [11,40]. Although single-stranded (ss) nucleic acids are rapidly degraded in serum or inside cells, ds nucleic acids are more stable than their ss counterparts; however, ds nucleic acids, including siRNAs, are still degraded and must be protected from endogenous nucleases in the bloodstream. Degradation can be avoided by the use of a suitable delivery system or by the nuclease-resistant chemical modification of the siRNA [10]. One approach involves the modification of the 2’-position of the ribose of the siRNA. Sugar modifications such as 2’-O-methylation,
2′-O-methoxyethylation, and 2′-fluoro-2′-deoxynucleoside modification can improve nuclease resistance [41,42]. Another approach involves the replacement of certain siRNA ribonucleotides with their deoxyribonucleotide counterparts.

We generated a DNA-chimeric siRNA, and substituted six basepairs from the 5′ end of the guide strand with their deoxyribonucleotide counterparts. This DNA-chimeric siRNA was more stable in human serum than the non-chimeric siRNA and showed resistance to endogenous nucleases. Moreover, the chimeric siRNA against PLK-1 decreased PLK-1 expression almost as effectively as the non-chimeric siRNA, and inhibited the proliferation of MM cells through the induction of apoptosis by cleaving caspase-3. These anti-neoplastic effects in the present study are consistent with our previous reports [19,20]. PLK-1 is overexpressed in MM cells compared to normal fibroblasts and, therefore, PLK-1 is a novel target that inhibits the proliferation of MM cells. Ui-Tei et al. [13] also demonstrated that DNA-chimeric siRNAs, in which the eight ribonucleotides from the 5′ end of the guide strand were substituted with deoxyribonucleotides, effectively induced gene-silencing without exerting the off-target effects. Our findings, taken together with the Ui-Tei’s report, demonstrate that DNA-chimeric siRNAs result in safe and more effective gene-silencing and that the DNA-chimeric siRNA is much suitable for an in vivo administration. Further
studies are warranted to evaluate the therapeutic potential of the DNA-chimeric siRNA

in vivo.

ZOL, a third-generation BP, inhibits the activity of farnesyl diphosphate synthase in the mevalonate pathway, resulting in inhibition of the prenylation of small GTPases [24,25]. The prenylated small GTPases including Ras, Rap-1, and Rho proteins transduce signals downstream for cell functions such as cell proliferation, adhesion, and migration [43-45], while the inhibition of these small GTPase prenylation by BPs results in the suppression of cancer progression [26-30,46-48]. In the present study, we have revealed that ZOL also inhibits the proliferation of MM cells. Treatment of MM cells with ZOL inhibited the prenylation of Rap-1A, Ras, and RhoA proteins, and induced apoptosis by cleaving capsase-3. Other investigators have also reported that ZOL inhibits the proliferation of MM cells [49,50]. Interestingly, one report demonstrated that Ca\(^{2+}\) regulates the growth inhibitory effects of BPs on MM cells [49]. Calcification is a well-known feature in MM [51,52], and BPs accumulate rapidly in bone [24,25]. We have demonstrated previously that ZOL has antitumor effects against osteosarcoma [29,46]. These findings collectively suggest that malignancies with ossifying features, including MM and breast cancers [48], are suitable candidates for ZOL treatment.
PLK-1 regulates cell division at several points during the mitotic phase, and RhoA is also implicated in the regulation of cytokinesis. Prenylated Rho proteins are delivered to the plasma membrane and are concentrated at the cleavage furrow of the cell during the M phase of cell cycle [53,54]. PLK-1 regulates the local activation of RhoA to promote cytokinesis [38,39] and, therefore, we hypothesized that ZOL treatment would augment the cytotoxic efficacy of the PLK-1 siRNA in MM cells. The combined ZOL and PLK-1 siRNA treatment showed synergistic effects at both low (Fa 0.5) and high (Fa 0.8) concentrations.

In conclusion, a DNA-chimeric PLK-1 siRNA inhibited cellular proliferation and induced apoptosis in MM cells, and a combination of PLK-1 siRNA and ZOL treatment revealed synergistic inhibitory effects on MM cells. The observation reported in the present study indicates that PLK-1 is a novel target for the treatment of MM and that the DNA-chimeric siRNA against PLK-1 combined with ZOL treatment would be an attractive strategy in the fight against this aggressive disease.

Supplementary Figure legend

Supplementary Figure 1. Evaluation of unprenylated RhoA expression in H2452 (left panel) and H28 (right panel) mesothelioma cells by the treatment of PLK-1 siRNA alone in combination with ZOL. Cells were incubated for 72 hours with PLK-1 siRNA (50 nM) alone in combination with ZOL (50 μM). Immunoblotting and immunoprecipitation were performed as described in Materials and Methods.

Supplementary Figure 1.
