Abstract

In order to synthesize a sugar ester at high concentration, 1,2-O-isopropylidene-α-D-glucofuranose (IpGlc), which is one of the sugar acetals and is more hydrophobic than unmodified glucose, was esterified with palmitic acid at 40°C using immobilized lipase from Candida antarctica in some organic solvents or their mixtures. A mixture of acetone and t-butyl alcohol as a reaction medium greatly improved both the initial reaction rate and yield at 80 h. The product concentration reached the maximum value (240 mmol/kg-solvent; ca. 110 g/kg-solvent) when 400 mmol/kg-solvent IpGlc and 1200 mmol/kg-solvent palmitic acid were used in acetone/t-butyl alcohol at 75/25 (v/v).

Keywords Esterification, lipase, solvent mixture, sugar acetal, sugar ester
Introduction

Sugar esters have been used as emulsifiers. They have been produced so far by chemical synthetic methods, in which many kinds of products (regioisomers with different acylation degree) are formed. Lipase-catalyzed esterification (dehydrative condensation) of sugar with fatty acid is one of the most favorable ways to synthesize sugar esters acylated at a specific position. Although there are many studies dealing with lipase-catalyzed syntheses of various kinds of sugar esters in organic solvents (Cramer et al. 2007; Ferrer et al. 2005; Šabeder et al. 2006; Walsh et al. 2009), their industrialization has not been realized yet. One of the reasons is low productivity or product concentration due to the low solubility of sugars in an organic solvent (Flores et al. 2005). This drawback may be overcome by using a less polar sugar derivative as a hydroxyl donor instead of an unmodified sugar.

There are many sugar derivatives such as alkyl glycosides, boronic acid esters, and sugar acetals. Although alkyl glycosides are one of the popular sugar derivatives, selective dealkylation is relatively difficult after esterification. On the other hand, sugar acetals or boronic acid esters are easily deprotected. There are some studies dealing with esterification of these derivatives (Fregapane et al. 1991; Sarney et al. 1994; Skagerlind et al. 1997). Because an isopropylidene derivative, one of the sugar acetals, is more popular than others, its use is appropriate for esterification. However, optimization of reaction conditions, such as substrate concentrations and selection of a reaction medium, has been insufficient. Therefore, in this study, we performed esterification of
1,2-O-isopropylidene-α-D-glucofuranose (IpGlc) with palmitic acid to form 6-O-palmitoyl-1,2-O-isopropylidene-α-D-glucofuranose (C16-IpGlc), and high product concentration could be achieved in a mixture of acetone and t-butyl alcohol (TBA) with improvements in the reaction rate and maximum yield.

**Materials and Methods**

**Materials**

Immobilized lipase from *Candida antarctica* (fraction B, CHIRAZYME® L-2, cf.-C2) was obtained from Roche Diagnostics, Mannheim, Germany. IpGlc was purchased from Sigma-Aldrich, MO, USA, and palmitic acid and other reagents were from Wako Pure Chemical Industries, Osaka, Japan.

Synthesis of 6-O-palmitoyl-1,2-O-isopropylidene-α-D-glucofuranose

Reaction media were acetone, acetonitrile, TBA, hexane, toluene, diisopropyl ether (DIPE), *N,N*-dimethyl formamide (DMF), and dimethyl sulfoxide (DMSO). Prior to esterification, these organic solvents were dehydrated over 4A molecular sieve for at least 3 days. Given amounts of IpGlc (0.25 mmol is typical) and palmitic acid (0.75 mmol is typical) were weighed into a glass vial,
and an organic solvent (5 mL) was added. The vial was tightly screw-capped and pre-incubated at
40°C for 10 min to solubilize the substrates. Immobilized lipase (50 mg) was then added. The vial
was vigorously shaken at 40°C and 130 rpm. At appropriate intervals, the reaction mixture was
analyzed with an HPLC.

Synthesis of C16-IpGlc without any organic solvent was also performed. A mixture of IpGlc
(0.25 mmol) and palmitic acid (0.25 mmol) was heated at 70°C to melt palmitic acid and was then
cooled down to 40°C prior to addition of 50 mg immobilized lipase. The reaction conditions were the
same as those in an organic solvent system.

Analysis of the product

The concentration of C16-IpGlc was determined by an HPLC equipped with a pump
(LC-10ADVP, Shimadzu, Kyoto, Japan) and a UV detector (SPD-10AVVP, Shimadzu) at 220 nm.
The reaction mixture (5 µL) was injected and eluted through an ODS column (J’sphere ODS-M80, 3
× 150 mm, YMC, Kyoto, Japan) with methanol/water at 90/10 (v/v) at 0.4 mL/min.

Product purification

The reaction mixture containing C16-IpGlc, unreacted substrates (IpGlc, palmitic acid), and a
small amount of by-product was concentrated by evaporation after removing immobilized lipase by
filtration. The evaporation residue was dissolved in ethyl acetate, and palmitic acid and IpGlc were removed by extraction with 0.1 mol/L sodium hydroxide aqueous solution. After separation of the organic and aqueous phases, the organic phase was dehydrated over anhydrous sodium sulfate followed by solvent evaporation. The residue was recrystallized twice in hexane to obtain C16-IpGlc. The product was identified by $^1$H-NMR (ECP-500, JEOL, Tokyo, Japan).

The by-product was recovered from the supernatant obtained during recrystallization. The supernatant was condensed by evaporation, and the residue was applied on a column (20 × 300 mm) packed with silica gel (Wakogel C-200, Wako). Elution was performed by hexane/ethyl acetate at 40/60 (v/v). The crude by-product was further purified by a semi-preparative HPLC equipped with a pump (LC-10ADVP) and a UV detector (SPD-10AVVP) at 220 nm. The column was J’sphere ODS-M80 (10 × 250 mm, YMC), and the eluent was methanol/water=85/15 (v/v) at 2 mL/min.

Results and Discussion

Screening of the reaction medium

Esterification yields at 20 h using substrates at equimolar concentrations (66 mmol/kg-solvent (ca. 50 mmol/L)) were 62%±2.1% (mean ± SD, n=3) in acetonitrile, 46%±1.5% in acetone, and 35%±1.4% in TBA, where yields were defined based on a molar basis of IpGlc, a limiting reactant. Because standard deviations were not large, following experiments were performed in $n=1$. Although
esterification proceeded the most in acetonitrile, the reaction mixture was opaque due to low IpGlc solubility. Therefore, it is difficult to increase the product concentration in acetonitrile. Low or trace yields could be achieved in toluene, hexane, DIPE, DMSO, and DMF. This may be due to the very low IpGlc solubility in toluene, hexane, and DIPE, while in DMF and DMSO, lipase may be inactivated by removing water which is essential to maintain its activity (Krishna et al. 2001).

In the reaction without any solvent, esterification proceeded only slightly at 40°C. The main reason would be low immiscibility between IpGlc and palmitic acid. Fregapane et al. (1991) reported that the reaction proceeded using immobilized lipase from *Rhizomucor miehei* without any solvent at high temperature (75°C). Addition of an organic solvent would therefore contribute to lower the reaction temperature to moderate level. Based on these results, following studies were performed only in acetone, TBA, or their mixtures.

Esterification in acetone or TBA

The main product was identified to be 6-O-palmitoyl-1,2-O-isopropylidene-α-D-glucofuranose (I) by NMR (1H and 1H-1H COSY, Scheme 1).

1H NMR: δ (ppm, CDCl3, TMS, 500 MHz, 298K) 0.88 (3H, t, J=7.1 Hz, 1’-CH3), 1.25 (27H, m, acetal-CH3, 2’~13’-CH2), 1.49 (3H, s, acetal-CH3), 1.63 (2H, m, 14’-CH2), 2.37 (2H, t, J=7.8 Hz, 15’-CH2), 4.08 (1H, m, 4-CH), 4.23 (2H, m, 6-CH2), 4.36 (1H, d, J=2.5 Hz, 3-CH), 4.43 (1H, m, 5-CH), 4.54 (1H, d, J=3.7 Hz, 2-CH), 5.96 (1H, d, J=3.7 Hz, 1-CH). The results indicate that the
6-O-position of IpGlc is esterified and that this structure is identical to the product obtained by esterification using lipase from *Rhizomucor miehei* (Fregapane et al. 1991). In this study, however, a small amount of by-product (<8% of product (1)) was detected (Fig. 1). The by-product, the formation of which has not been reported, was a regioisomer that was esterified at the 5-O-position of IpGlc. The structure of the regioisomer (5-O-palmitoyl-1,2-O-isopropylidene-α-D-glucofuranose (2)) was identified; $^1$H NMR: δ (ppm, CDCl$_3$, TMS, 500 MHz, 298K) 0.87 (3H, t, $J=7.1$ Hz, 1’-CH$_3$), 1.24 (27H, m, acetal-CH$_3$, 2’~13’-CH$_2$), 1.49 (3H, s, acetal-CH$_3$), 1.62 (2H, m, 14’-CH$_2$), 2.39 (2H, m, 15’-CH$_2$), 3.95 (2H, m, 6-CH$_2$), 3.99 (1H, d, $J=1.9$ Hz, 3-CH), 4.11 (1H, dd, $J_1=1.9$ Hz, $J_2=9.3$ Hz, 4-CH), 4.56 (1H, d, $J=3.6$ Hz, 2-CH), 4.95 (1H, m, 5-CH), 5.91 (1H, d, $J=3.6$ Hz, 1-CH).

Figure 2 shows the time courses for the syntheses of C16-IpGlc at different molar ratios of palmitic acid and IpGlc in acetone and TBA. In TBA, esterification proceeded faster and reached almost the maximum yield within 8 h. However, slight decreases in the yield were observed after long-term reaction. This would be due to the formations of diester (Zhang et al. 2003) and/or regioisomer (2) by transesterification from the 6-O- to the 5-O-position. Meanwhile, it took 1-2 days to reach the maximum yield in acetone. However, the maximum yield in acetone was higher than that in TBA at any molar ratio. The low yield in TBA would be attributed to the strong interaction between palmitic acid and TBA, which shifts the reaction equilibrium toward hydrolysis (Kobayashi et al. 2003). Conversely, it indicates that the interaction of palmitic acid with acetone is relatively weaker than that with TBA. Because the maximum yield leveled off when a 3 times or greater amount of palmitic acid was used both in acetone and TBA, the molar ratio of palmitic acid to IpGlc
was adjusted to be 3:1.

Reaction in the mixed solvent

The maximum yield was higher in acetone, although esterification was faster in TBA. Therefore, the use of a mixture of these two solvents may improve both the reaction rate and maximum yield. Figure 3 shows the dependence of the initial reaction rate and yield at 80 h on the volumetric fraction of TBA, $f_{\text{TBA}}$, in the mixed solvent. When a small amount of TBA ($f_{\text{TBA}} \leq 0.25$) was added to acetone, the initial reaction rate steeply increased, and it increased gradually at $f_{\text{TBA}}$ greater than 0.25. The initial rate was 8.4 μmol/min/(g-immobilized lipase) at $f_{\text{TBA}} = 0.25$ and was 5.9 times higher than that in acetone (1.4 μmol/min/(g-immobilized lipase)). These results suggest the activation of lipase in TBA.

Meanwhile, the yield at 80 h became lower with an increase in the volumetric fraction of TBA. When the reaction was performed in TBA, the yield was ca. 42%, although it was ca. 70% in acetone. Mixed solvents gave 50-70% yields. These results may indicate that interaction between TBA and palmitic acid is gradually weakened by the addition of acetone as a diluent. The mixture of TBA and acetone at 25/75 (v/v) is a promising solvent to improve both the reaction rate and yield at 80 h.

Optimization of the product concentration
To improve the product concentration, esterification was performed at different initial concentrations of IpGlc (66-400 mmol/kg-solvent) at a constant molar ratio of palmitic acid to IpGlc (3:1) in acetone/TBA (75/25, v/v). The initial rate steeply decreased with an increase in initial IpGlc concentrations lower than 200 mmol/kg-solvent (Fig. 4a). Although this reason is not clear, a possible one may be a change in the nature of the reaction mixture as a solvent because substrates themselves can act as solvents at high substrate concentration. Meanwhile, the initial rate was almost constant at the initial IpGlc concentrations higher than 200 mmol/kg-solvent because the IpGlc concentration reached saturation.

Although the yield at 24 h, which may be an indication of lipase activity (Fig. 4b), showed the same tendency as the result in Fig. 4a, the maximum yield during the 20-day reaction was 61-72%. The maximum product concentration was calculated to be 240 mmol/kg-solvent (ca. 110 g/kg-solvent) when 400 mmol/kg-solvent IpGlc and 1200 mmol/kg-solvent palmitic acid were used, and the maximum yield gradually decreased with the increase in initial IpGlc concentration. Previously, a change in the equilibrium yield was observed in a reaction system without any organic solvent for the synthesis of L-menthyl oleate (Kobayashi et al. 2007). The phenomenon observed in this study resembles the previous one and suggests that the reaction shifted slightly toward hydrolysis.

In conclusion, lipase-catalyzed synthesis of C16-IpGlc in a mixture of acetone and TBA was successfully performed with good yield at moderate temperature. Use of the solvent mixture
improved both the reaction rate and maximum yield. Although the reaction rate was slower at higher substrate concentration, high product concentration could be achieved at high IpGlc concentration.
