Abstract

Human T-cell leukemia virus type 1 (HTLV-1) is the causal agent of a neoplastic disease of CD4+ T cells, adult T-cell leukemia (ATL), and inflammatory lung diseases including HTLV-1 associated myelopathy/tropical spastic paraparesis, dermatitis, and inflammatory lung diseases. ATL cells, which constitutively express CD25, resemble CD25+CD4+ regulatory T cells (Treg). Approximately 60% of ATL cases indeed harbor leukemic cells that express FoxP3, a key transcription factor for Treg cells. HTLV-1 encodes an antisense transcript, HTLV-1 bZIP factor (HBZ), which is expressed in all ATL cases. In this study, we show that transgenic expression of HBZ in CD4+ T cells induced T-cell lymphomas and systemic inflammation in mice, resembling diseases observed in HTLV-1 infected individuals. In HBZ-transgenic mice, CD4+Foxp3+ Treg cells and effector/memory CD4+ T cells increased in vivo. As a mechanism of increased Treg cells, HBZ expression directly induced Foxp3 gene transcription in T cells. The increased CD4+Foxp3+ Treg cells in HBZ transgenic mice were functionally impaired while their proliferation was enhanced. HBZ could physically interact with Foxp3 and NFAT, thereby impairing the suppressive function of Treg cells. Thus, the expression of HBZ in CD4+ T cells is a key mechanism of HTLV-1-induced neoplastic and inflammatory diseases.

Introduction

Human T-cell leukemia virus type 1 (HTLV-1) was the first human retrovirus associated with human diseases including adult T-cell leukemia (ATL) [1,2] and HTLV-1 associated myelopathy/tropical spastic paraparesis (HAM/TSP) [3,4]. One of the virological attributes of HTLV-1 is that it transmits mainly by cell-to-cell contact [5,6]. Therefore, HTLV-1 induces the proliferation of infected CD4+ T cells to increase further transmission [7]. HTLV-1 encodes several regulatory and accessory genes in the pX region located between the env and the 3' LTR [7,8]. Among the viral genes, tax possesses in vitro transforming activity and can induce cancers in transgenic (Tg) animals via its pIgotropic actions [9,10]. Yet the expression of Tax is frequently disrupted in ATL [7]. In contrast, the HTLV-1 bZIP factor (HBZ) gene, which is encoded in the minus strand of the HTLV-1 genome [11,12], is transcribed in all ATL cases [13]. Recently, it has been reported that APOBEC3G generates nonsense mutations in all HTLV-1 genes except HBZ [14], suggesting that the HBZ gene is indispensable for the growth and/or survival of ATL cells and HTLV-1 infected cells. The HBZ gene product promotes the proliferation of ATL cells [13,15]. Further, HBZ mRNA expression in HAM/TSP patients was well correlated with disease severity [16]. These findings suggest that HBZ has a critical role in the development of ATL and HAM/TSP.

It has been shown that ATL cells functionally and phenotypically resemble Foxp3+ CD25+CD4+ regulatory T (Treg) cells, which control immune responses against self- and non-self-antigen [17]. ATL cells constitutively express CD25 and scarcely produce interleukin-2 (IL-2) [18,19]. Furthermore, two thirds of ATL cases harbor leukemic cells expressing FoxP3 [20,21], a key transcription factor for the generation and function of Treg cells [22,23,24]. In HTLV-1 carriers, HTLV-1 provirus is detected mainly in CD4+ effector/memory T cells and Treg cells [25,26,27]. Thus, HTLV-1 favors Treg cells and effector/memory T cells in vivo, and transforms them. However, how HTLV-1 targets these T cell subpopulations remains to be elucidated.

In this study, we show that transgenic expression of HBZ increases Foxp3+ Treg cells and effector/memory T cells, leading to development of T-cell lymphomas and systemic inflammatory diseases. In addition, the suppressive function of Treg cells is severely impaired in HBZ transgenic mice. At the molecular level, we show that HBZ interacts with Foxp3 and NFAT, interrupting the function of each molecule, and leading to the deregulation of Foxp3-mediated transcriptional control of the genes associated
Human T-cell leukemia virus type 1 (HTLV-1) is the first retrovirus that is associated with human diseases including an aggressive leukemia derived from CD4+ T cells, adult T-cell leukemia (ATL), and chronic inflammatory diseases of the central nervous system, lung, or skin. However, it remains to be elucidated how HTLV-1 induces these diseases. A viral gene, Tax, has been considered as a critical player in HTLV-1 pathogenesis, yet Tax expression is frequently lost in ATL cells. Another viral gene, HBZ, is constitutively expressed in both HTLV-1 infected cells and ATL cells. However, it remains unknown how HBZ functions in the HTLV-1-related diseases. We show here that the HBZ induced T-cell lymphoma and chronic inflammation in vivo similar to those in HTLV-1 infected individuals, indicating an important role of HBZ in HTLV-1 associated human diseases. As observed in HTLV-1 infected individuals, effector/memory and regulatory CD4+ T cells were increased in the HBZ-transgenic mice. Further, HBZ could interact with host transcription factors, Foxp3 and NFAT, leading to dysregulation of Treg function. The Treg dysregulation induced by HBZ is thought to be a critical mechanism of the HTLV-1 pathogenesis. This study sheds light on the HTLV-1 associated pathogenesis and provides an important clue to prevent or treat the human diseases.

Results

HBZ transgenic mice spontaneously develop inflammatory lesions in the skin and lung

Since HTLV-1 mainly infects CD4+ T cells in vivo, we generated Tg mice expressing the HBZ gene under the control of the murine CD4-specific promoter/enhancer/silencer (Figure S1) [15]. We analyzed the HBZ transgenics (Figure S1) and their expression in the three lines generated. HBZ gene expression was specifically detected in CD4+ T cells (Figure 1A). HBZ protein was also detected in these transgenic mice (Figure 1B). The level of HBZ gene transcripts in line 12 was the most abundant but similar to that of endogenous expression of the HBZ gene in ATL cell lines (Figure 1C). Therefore, unless specifically described, we used line 12 in this study. Notably, the majority of HBZ-Tg mice developed skin lesions by 18 weeks of age, in contrast with no disease in non-transgenic littermates (non-Tg mice) (Figure 1, D and E). Histological analyses revealed infiltration of CD3+CD4+ T cells into the dermis and epidermis, and also the alveolar septa of the lung (Figure 1, F, G and S2), whereas no obvious evidence of inflammation in other tissues, including liver, kidney, muscle, heart, stomach, spinal cord, intestines and brain. Since massive infiltration of lymphocytes in the skin and lung was observed in line 9 and 12, but not in line 2, level of HBZ expression is likely associated with these phenotypes. Thus, HBZ-Tg mice spontaneously developed dermatitis and alveolitis. Similar lesions have been observed in HTLV-1 carriers, especially in those harboring large numbers of infected cells [20,29].

HBZ-Tg mice develop T-cell lymphoma after a long latent period

To study the growth-promoting activity of the HBZ gene, we assessed the proliferation of CD4+ T cells in HBZ-Tg mice by incorporation of bromodeoxyuridine (BrdU), and found that the proliferation was three fold-higher than in non-Tg mice, whereas the proliferation of CD8+ T cells or B cells was not altered (Figure 2A, Table S1A). Transgenic expression of HBZ enhances the in vivo proliferation of mouse T cells, as ectopic expression of HBZ enhances the proliferation of human T cells [13,15]. It is known that HTLV-1 transforms CD4+ T cells after a long latent period in a fraction of asymptomatic carriers [7]. Analogous to the development of ATL in humans, 14 of 37 (37.8%) HBZ-Tg mice of all three-founder lines developed T-cell lymphomas after 16 months, in contrast with 27 non-Tg mice (7.4%) (P<0.001 by the logrank test) (Figure 2B). In some transgenic mice, lymphoma cells infiltrated various organs including the lung, bone marrow, spleen and liver (Figure 2C). All of the lymphomas in HBZ-Tg mice were CD3+ and CD4+ by immunohistochemical analyses when examined before the mice became moribund (Figure 2D). Lymphoma cells also expressed TCRβ cell receptors on their surfaces (Figure S3). Monoclonal proliferation of these lymphomas was shown by single strand conformation polymorphism in Vγ2-Jγ1 junction region of T cell receptor γchain gene (Figure S4). Notably, the primary lymphoma cells expressed Foxp3 at various intensities in the majority of cases (Figure 2E, Table 1), exhibiting a similar Foxp3 staining pattern to that in lymph nodes in human ATL cases (Figure S5). Thus, the T-cell lymphomas in HBZ-Tg mice phenotypically resemble ATL, suggesting that HBZ promotes proliferation of CD4+ T cells and predisposes cells to transform in due course.

Increased effector/memory and regulatory CD4+ T cells in HBZ-Tg mice

To study the cellular basis of the lymphomagenesis and inflammation in HBZ-Tg mice, we analyzed the phenotype and function of T cells, especially Treg cells, in 3-month-old HBZ-Tg line 12 mice before their pathological manifestations. CD41highCD62Llow effector/memory CD4+ T cells increased in HBZ-Tg mice (Figure 3A). CD4 single positive T cells also increased in the thymus (Figure S6). Further, not only the ratio but also the absolute number of Foxp3+ T cells was markedly increased in HBZ-Tg mice compared with non-Tg mice, while the numbers of CD8+ T cells were equivalent (Figure 3, B and C). Increased Treg cells were also observed in thymus, lymph node and peripheral blood mononuclear cells (Figure 3D and Figure S7). We also observed the increased Treg cells and effector/memory T cells in the HBZ-Tg line 2 (Figure S8), which showed quite lower expression of HBZ than line 12 (Figure 1C). The proportion of Treg cells in skin and lung was rather low compared with that in spleen (Figure 3B and S2), indicating that Foxp3+ T cells are predominant in the infiltrating T cells.

This result indicates that transgenic expression of HBZ induces systemic inflammation despite an increase in Foxp3+ Treg cells. It has been reported that IL-2 is critical in the homeostasis of Treg cells [30]. To study mechanisms by which HBZ expression increases Treg cells, we analyzed IL-2 production in the CD4+ T cells of HBZ-Tg mice after stimulation by PMA and ionomycin. IL-2 production was not augmented in either the Foxp3+ or Foxp3- populations from HBZ-Tg mice (Figure S9), indicating that the increase in the number of Treg cells was not due to enhanced IL-2 production.

Previous studies showed that Tax is a critical viral protein for the pathogenesis of HTLV-1. Therefore, we generated Tax transgenic (tax-Tg) mice using the same promoter/enhancer/silencer. In the tax-Tg mice, we did not observe increased effector/memory T cells or Treg cells (Figure S10). Thus, this increase in effector/memory T cells and Treg cells was specific to HBZ and HTLV-1 bZIP Factor Induced Pathogenesis

Author Summary

With Treg functions. These results indicate that HBZ plays a critical role in neoplastic and inflammatory diseases arising from HTLV-1 infection.

Human T-cell leukemia virus type 1 (HTLV-1) is the first retrovirus that is associated with human diseases including an aggressive leukemia derived from CD4+ T cells, adult T-cell leukemia (ATL), and chronic inflammatory diseases of the central nervous system, lung, or skin. However, it remains to be elucidated how HTLV-1 induces these diseases. A viral gene, tax, has been considered as a critical player in HTLV-1 pathogenesis, yet Tax expression is frequently lost in ATL cells. Another viral gene, HBZ, is constitutively expressed in both HTLV-1 infected cells and ATL cells. However, it remains unknown how HBZ functions in the HTLV-1-related diseases. We show here that the HBZ induced T-cell lymphoma and chronic inflammation in vivo similar to those in HTLV-1 infected individuals, indicating an important role of HBZ in HTLV-1 associated human diseases. As observed in HTLV-1 infected individuals, effector/memory and regulatory CD4+ T cells were increased in the HBZ-transgenic mice. Further, HBZ could interact with host transcription factors, Foxp3 and NFAT, leading to dysregulation of Treg function. The Treg dysregulation induced by HBZ is thought to be a critical mechanism of the HTLV-1 pathogenesis. This study sheds light on the HTLV-1 associated pathogenesis and provides an important clue to prevent or treat the human diseases.
not associated with similar transgenic expression of tax in this transgenic model system.

We next analyzed the phenotype and function of the increased Foxp3+ Treg cells in HBZ-Tg mice. CD4+Foxp3+ T cells of HBZ-Tg mice expressed Treg-associated molecules, such as cytotoxic T-lymphocyte associated antigen-4 (CTLA-4), glucocorticoid-induced TNF receptor family-related-protein (GITR), CD103, and CD25 [31]; yet the expression levels of CTLA-4, GITR and CD25 were lower than those of Foxp3+ T cells in non-Tg mice (Figure 3, B and E, Table S1B). In contrast, both Foxp3+ and Foxp3-CD4+ T cells of HBZ-Tg mice expressed CCR4 and CD103 at higher levels than those in non-Tg mice, suggesting that this might contribute to the migration and infiltration of HBZ-Tg CD4+ T cells into the skin (Figure 1F) [32,33]. Further, it is of note that the in vitro suppressive function of HBZ-Tg Treg cells was severely impaired. When CD4+GITRhigh T cells, which were >90% Foxp3+ [23], from HBZ-Tg or non-Tg mice were co-cultured with CD4+CD25+ T cells from wild-type mice and stimulated with Con A or anti-CD3 antibody, HBZ-Tg Treg cells were much less suppressive (Figure 3F). These results indicate that HBZ expression increases functionally impaired Treg cells.

Next, we assessed the proliferation of CD4+ T cells in HBZ-Tg mice. BrdU incorporation of Foxp3+ as well as Foxp3-CD4+ T cells from HBZ-Tg mice was also significantly higher than those in non-Tg mice (Figure 3G). In general, proliferation of Treg cells in response to mitogenic stimulation is suppressed in vitro. However, Foxp3+ T cells from HBZ-Tg mice proliferated more vigorously in vitro in response to anti-CD3 antibody than did non-Tg Foxp3+ T cells (Figure 3H). Thus, transgenic expression of HBZ in CD4+ T cells induces the expansion of Foxp3+ Treg cells, yet impairs their suppressive function.

**Figure 1.** HBZ-Tg mice spontaneously develop inflammatory diseases in skin and lung. (A) Cell-type specific transcription of the transgene in line 12 was confirmed by RT-PCR in each sorted cell population. (B) The expression of HBZ protein in CD4+ splenocytes was confirmed by Western blotting. (C) Transcripts of the HBZ gene in CD4+ splenocyte of HBZ-Tg mice or ATL cell lines were quantified by real time PCR. ATL-43T and MT-1 are derived from ATL cells. (D) An HBZ-Tg mouse with typical skin symptom (Arrow indicates skin lesion). (E) The incidence of dermatitis in HBZ-Tg (line 12) and non-Tg mice. (F and G) Histological findings of the skin and the lung in HBZ-Tg mice. Lymphocytes massively infiltrated the dermis and epidermis (F) and the alveolar septum (G) (Arrows present infiltration of lymphocytes). Infiltration of CD3+CD4+ T cells into these tissues was shown by immunohistochemistry compared with non-Tg mice as control.

doi:10.1371/journal.ppat.1001274.g001
HBZ directly induces Foxp3 expression in a CD4+ T-cell intrinsic manner

To study whether HBZ increases Foxp3+ Treg cells in a cell intrinsic manner, we expressed HBZ in naive CD4+ T cells in vitro using a retrovirus vector (Figure 4A). Interestingly, HBZ induced Foxp3 expression in 16.8% of HBZ expressing T cells, which is a similar enhancement to that due to TGF-β treatment (14.8%). The expression was markedly augmented in HBZ expressing T cells treated with TGF-β (72.2%) (Figure 4B). A reporter assay using the enhancer and promoter of the Foxp3 gene [34] demonstrated that HBZ induced transcription of the Foxp3 gene (Figure 4C), which was enhanced in the presence of TGF-β. Thus, HBZ-induced Foxp3 expression could be a mechanism for the increase of Foxp3+ T cells in HBZ-Tg mice.

HBZ physically interacts with Foxp3

Previous studies have shown that Foxp3 controls Treg function by cooperating with transcription factors including NFAT [35] and AML-1/Runx1[36]. Impaired interactions of Foxp3 with these factors not only alter the suppressive function of Treg cells but also suppress the expression of Treg associated molecules, such as CD25, CTLA-4, and GITR [23,35,36,37], which is similar to the
phenotype observed in HBZ-Tg mice (Figure 3, B and E). These findings prompted us to assess the possibility that HBZ might be involved in Foxp3-dependent transcriptional regulation. To address this, we first examined direct interaction among HBZ, NFAT and Foxp3. Immunoprecipitation experiments showed that HBZ physically interacted with both NFAT and Foxp3 (Figure 5A). Moreover, to study the interaction of endogenous HBZ and Foxp3, we performed immunoprecipitation using ATL-43T, a Foxp3-expressing ATL cell line. An anti-HBZ antibody co-precipitated endogenous Foxp3 in the ATL-43T cells, demonstrating that the interaction occurs not only in an enforced overexpressed state but also under physiological conditions (Figure 5B).

It has been previously reported that human FoxP3 protein migrates as a doublet, which coincides with this result [38]. Analyses using HBZ deletion mutants showed that the central domain of HBZ interacted with Foxp3 (Figure 5C). Experiments with Foxp3 deletion mutants revealed that the forkhead (FH) domain of Foxp3 (Figure 5D). It has been reported that the region between the forkhead domain and the leucine zipper domain of Foxp3 interacted with AML-1 [36]. HBZ did not inhibit the binding between Foxp3 and AML-1 nor the suppressive effect of Foxp3 on AML-1-mediated transcription from the IL-2 gene promoter (Figure S11), indicating that HBZ does not influence Foxp3/AML1 mediated gene regulation.

To study whether HBZ independently interacts with Foxp3 and NFAT or, alternatively, if these molecules form a ternary complex, we studied the effect of the DNA intercalator ethidium bromide (EtBr) on their interactions. As shown in Figure 5E, the interactions of HBZ with Foxp3 or NFAT were not affected by EtBr while the interaction between NFAT and Foxp3 was diminished by EtBr as reported previously [35]. These findings suggest that the interactions of HBZ with NFAT and Foxp3 are independent of DNA while the interaction between NFAT and Foxp3 requires the presence of DNA.

HBZ inhibits Foxp3-mediated CTLA-4 and GITR expression in CD4+ T cells in vitro

In HBZ-Tg mice, the expression of Treg-associated molecules including CTLA-4, GITR and CD25 was suppressed when compared with their expression in Treg cells from non-Tg mice (Figure 3B and E). This finding may account for the impaired function of Treg cells since these molecules, in particular CTLA-4, play a critical role in Treg-mediated suppression [39]. To further study the effect of HBZ on the expression of Treg-associated molecules, we transduced HBZ along with Foxp3 into naive CD4+ T cells in vitro using retrovirus vectors (Figure 4A). HBZ expression suppressed Foxp3-induced GITR and CTLA-4 expression whereas it did not inhibit CD25 expression (Figure 6A). Expression of HBZ alone increased CD25 expression (Figure 6A), which might obscure the suppressive effect of HBZ under these conditions. Suppression of GITR and CTLA-4 expression required both the activation and the central domains of HBZ (Figure 6, B and C), which correspond to the binding sites of HBZ to Foxp3 (Figure 5C) and NFAT (Figure S12). Since both Foxp3 and NFAT are critical

Mice that died or became immobilized were subjected to autopsy. Tissue samples were surgically removed, fixed in 10% formalin in phosphate buffer, embedded in paraffin and stained with hematoxylin and eosin for histopathological examination. Tissue samples with lymphoma were subjected to immunohistochemical analysis (IHC) using monoclonal antibodies for CD3 (500A2), B220 (RA3-6B2), and Foxp3 (FJK-16s). The phenotype of lymphomas was determined based on CD3 and B220 expression. The degree of Foxp3 expression in lymphomas was evaluated by immunohistochemistry. (+, 1–9%; ++, 10–20%; +++, more than 20%) Frequency of T-cell lymphoma of each line is shown as follows; (number of T-cell lymphoma/number of total observed mice).
Figure 3. Transgenic expression of HBZ in CD4+ T cells increases Foxp3+ Treg cells with impaired suppressive function. (A and B) Mouse splenocytes were stained with the indicated antibodies, and analyzed by flow cytometry. Representative dot plots gated on the CD4+ population are shown. For these experiments, HBZ-Tg mice without any symptoms were used. Tables show the mean ± SD (n = 5 for A, n = 3 for B). (C) The absolute number of Foxp3+ or Foxp3− CD4+ T cells in HBZ-Tg and non-Tg mice. The results shown are the mean ± SD (n = 3). (D) Flow cytometric analysis for the Foxp3 expression in CD4 single positive thymocytes. Representative dot plots gated on the CD4 single positive population are shown from three independent analyses. (E) Flow cytometric analyses of CD4+ T cells for Treg related molecules. Numbers in dot plots indicate mean fluorescence intensity (MFI) of each molecule in the rectangular gates. (F) Suppressive activity of Treg cells from HBZ- or non-Tg mice on T-cell proliferation. Sorted Foxp3− T cells were cultured with CD4+CD25+ cells of non-Tg mice as responder cells for 72 h with ConA or soluble anti-CD3.

doi:10.1371/journal.ppat.1001274.g003

for Treg function [35], it is likely that HBZ suppresses the expression of GITR and CTLA-4 by interacting with Foxp3 and NFAT and thereby interfering with their transcriptional regulation in Treg cells. To examine suppressive effect of HBZ on expression of GITR, CTLA-4 and CD25, we isolated Treg cells from wild type mice and expressed HBZ using retroviral vectors. As shown in Figure 6D, HBZ suppressed endogenous expression of CD25, GITR and CTLA-4 in Treg cells, confirming that HBZ is responsible for suppressed expression of these molecules.

Discussion

HTLV-1 targets CD4+ T cells; cell central to immune regulation. In contrast to human immunodeficiency virus, which destroys CD4+ T cells, HTLV-1 increases its copy number by inducing clonal proliferation of infected cells in vivo [40,41]. Since HTLV-1 spreads mainly by cell-to-cell transmission [5], increased number of infected cells facilitates transmission of HTLV-1 to new cells. Recent studies showed that glucose transporter 1, heparan sulfate proteoglycans and neuropilin-1 are important for the entry of HTLV-1[42,43,44], consistent with the finding that this virus can infect a variety of cell types [45,46]. However, HTLV-1 provirus is detected mainly in the regulatory and effector/memory CD4+ T cells of HTLV-1 carriers (Figure S13) [25,26,27], which indicates that HTLV-1 favors these specific subpopulations of CD4+ T cells. These findings suggest that HTLV-1 induces proliferation and/or facilitates survival of the regulatory and effector/memory CD4+ T cells. The mechanism(s) by which HTLV-1 targets Treg cells, however, remained unclear until now. In this study, we showed that HBZ could enhance transcription of the Foxp3 gene, and also promote proliferation of Foxp3+CD4+ T cells in transgenic mice, indicating that HBZ enhances both the generation and proliferation of Foxp3+ T cells. Impaired Foxp3 function is associated with proliferation of Treg cells [37], so the HBZ-mediated Treg dysfunction may also contribute to Treg proliferation in addition to direct growth proliferation by the HBZ transcript [13]. Another possible explanation is that Treg cells might be more susceptible to HTLV-1 infection, since Treg cells proliferate vigorously in vivo presumably by recognizing self-antigen and commensal microbes [47]. With these strategies, HTLV-1 likely targets this specific T-cell population as its host, which might be beneficial for their survival.

As mechanisms of the HBZ-mediated effect on Foxp3 functions, we demonstrated that HBZ physically interacted with Foxp3 and impaired its function in vivo. HBZ lacking the Foxp3-binding region showed a slight inhibitory effect on Foxp3 function, indicating that direct interaction between HBZ and Foxp3 is, at least in part, responsible for suppression. The results of immunoprecipitation analyses using Foxp3 mutants showed that the forkhead domain of Foxp3 was responsible for the molecular interaction between HBZ and Foxp3. Since the forkhead domain is the DNA-binding domain of Foxp3 [17], HBZ might inhibit the transcriptional function of Foxp3 by interfering with the DNA binding activity. Foxp3 play a key role in the function and homeostasis of Treg cells [22,23,24], indicating that HBZ-mediated dysfunction of Foxp3 contributes to impaired Treg function in HBZ+Tg mice. This impaired Treg function allows non-regulatory T cells to become hyper-reactive to commensal microbes and self-antigens, provoking enhanced proliferation of non-regulatory T cells and T cell-mediated autoimmune/inflammatory disease. These data collectively suggest that the viral protein HBZ hijacks the transcriptional
machinery of host Treg cells leading to inflammatory disorders in the host. Conversely, Tax, another HTLV-1 protein, has been reported to suppress FoxP3 expression in human T cells in vitro [48]. Therefore, it is likely that both viral proteins target Foxp3 albeit with apparently different effects. Considering that HBZ is consistently expressed while Tax expression is sporadic, Tax might control excess expression of Foxp3 in HTLV-1 infected cells.

**Figure 5. HBZ physically interacts with Foxp3 and NFAT.** (A) The expression vectors of the indicated proteins were co-transfected into 293FT cells, and their interactions were analyzed by immunoprecipitation (IP). (B) Nuclear extract of ATL-43T cells was subjected to IP with anti-HBZ antibody or control IgG, and detected by anti-FoxP3 antibody. (C and D) The interactions of HBZ and Foxp3 were analyzed by IP using HBZ mutants (C) or Foxp3 mutants (D). A schematic diagram of Foxp3 mutants is shown. ZnF, zinc finger; LZ, leucine zipper; FH, forkhead domain. Asterisks (* or **) show responsible region for each molecular interaction. (E) The interactions among HBZ, Foxp3 and NFATc2 were analyzed with or without EtBr. doi:10.1371/journal.ppat.1001274.g005
Figure 6. HBZ inhibits Foxp3-mediated CTLA-4 and GITR expression in vitro. (A) Mouse CD4\(^+\)CD25\(^-\) T cells co-transduced with the retroviral vectors were stained with the indicated antibodies. Mean fluorescence intensity (MFI) of CD25, GITR, and CTLA-4 in GFP/NGFR double-positive cells are shown as mean ± SD for triplicate culture. *, \(P<0.01\); **, \(P<0.001\) by two-tailed Student t-test. (B and C) CD4\(^+\)CD25\(^-\) T cells transduced with the pMXs-Ig vector encoding wild-type or mutant HBZ, and pGCSamIN-Foxp3 vector were stained with anti-GITR (B) or anti-CTLA-4 (C).
In this study, we demonstrated that the characteristics of CD4⁺ T cells in HBZ-Tg mice resemble those of human ATL cells or HTLV-1-infected cells in carriers. First, the frequency of Foxp3 positive cells in T-cell lymphomas was similar in HBZ-Tg mice and in ATL [20]. Second, the suppressive function of Foxp3⁺ T cells was impaired in both ATL and HBZ-Tg mice [49]. Third, CD4⁺ T cells in HBZ-Tg mice, HTLV-1-infected cells in carriers, and ATL cells possess similar effector/memory and regulatory phenotypes [25,27]. As shown in this study, transgenic mice expressing Tax under the same promoter as the HBZ gene did not show any changes in the number of Foxp3⁺ T cells or effector/memory T cells. These data suggest that HBZ, rather than Tax, is responsible for the specific phenotype of HTLV-1-infected cells and ATL cells.

It has been reported that Tax transgenic animals develop tumors [50,51,52]. In these reports, Tax induces leukemic cells in ATL patients frequently lose Tax expression [7], whereas HBZ expression has been detected in all ATL cases studied so far [13]. We reported that the HBZ gene transcript is responsible for the oncogenic activity in vivo [13]. Taken together, our results suggest that HBZ is responsible for the specific phenotype, function, and proliferation of HTLV-1-infected CD4⁺ T cells and ATL cells, and that HBZ plays an important role in the oncogenic activity of HTLV-1 in addition to Tax. Further, the long latent period before the onset of T-cell lymphomas in HBZ-Tg mice suggests that additional genetic and/or epigenetic alterations in CD4⁺ T cells are necessary for the development of T-cell lymphomas in HBZ-Tg mice as well as for ATL.

In conclusion, the HBZ-mediated dysregulation of Treg function and proliferation that we report here provide novel insights into the interaction between the host and the virus and may be exploited to treat and prevent HTLV-1-induced diseases.

Materials and Methods

Ethics statement

This study was conducted according to the principles expressed in the Declaration of Helsinki. The study was approved by the Institutional Review Board of Kyoto University (E921). All patients provided written informed consent for the collection of samples and subsequent analysis. Animal experimentation was performed in strict accordance with the Japanese animal welfare bodies (Law No. 105 dated 19 October 1973 modified on 2 June 2006), and the Regulation on Animal Experimentation at Kyoto University. The protocol was approved by the Institutional Animal Research Committee of Kyoto University ( Permit Number: D009-3). All efforts were made to minimize suffering.

Mice and cell cultures

C57BL/6j mice were purchased from CLEA Japan. The HBZ cDNA was cloned into the Sall site of the H/M/T-CD4 vector, which was designed for restricted expression of a transgene in CD4⁺ cells. The purified fragment containing the HBZ transgene was microinjected into C57BL/6j F1 fertilized eggs. Transgenic founders were screened for the integration of transgenes in their genomic DNA by PCR and mated with C57BL/6j mice to generate transgenic progeny [13,15]. All HBZ-Tg mice were heterozygotes for the transgene. The phenotype of HBZ-Tg mice was stable in the different generations. They express the silenced HBZ gene under the control of the CD4-specific promoter/ enhancer/silencer.

Plasmids

In order to construct the vectors expressing tagged spliced HBZ and its mutants, their coding sequences were amplified by PCR, and cloned into the expression vector, pcDNA 3.1(−)/myc-His (Invitrogen). A cDNA clone that contains NFATc2 coding sequence was kindly provided by Kazusa DNA Research Institute. To construct the FLAG-tagged NFATc2 expression vector, its coding region was cloned into pCMV-Tag2 (Stratagene). pCMV-HA (Clontech) was used to generate HA-tagged Foxp3 expression vectors. The vectors expressing Flag-tagged Foxp3 mutants were also used for immunoprecipitation.

Antibodies and reagents

The following antibodies were used for immunoprecipitation and Western blotting: mouse anti-Flag (clone M2; Sigma, Saint Louis, MO), mouse anti-c-myc (clone 9E10;Sigma), mouse anti-HA (clone HA-7; Sigma), rabbit anti-His polyclonal antibody (MBL), rabbit anti-FOXp3 (polyclonal antibody; Abcam), and rabbit anti-HBZ polyclonal antisera [13].

The following antibodies were purchased from BD PharMin-gen; purified monoclonal antibody (mAb) for mouse CD4 (RM4-5), CD8α (53-6.7), CD25 (PC61), CD44 (IM7), CD103 (M290), and IL-2 (JES6-5H4). Purified monoclonal antibodies for mouse GITR (DTA-1), CTLA-4 (UC10-4B9), CD62L (MEL-14), TCRβ (H57-597), TCRγδ (eBioGL3) and Foxp3 (JFK-16s) or human Foxp3 (256A/E7) were purchased from eBioscience. Anti-mouse CCR4 antibody (polyclonal antibody; Caproligos) and FITC-labeled anti-goat IgG antibody (Santa Cruz Biotechnology) were used for the detection of mouse CCR4. The following reagents were used for cell culture: anti-CD3ε antibody (145-2C11; R&D systems), Con A (Sigma), PMA (Sigma), and ionomycin (Sigma).

Synthesis of cDNA and semiquantitative RT-PCR

cDNAs were synthesized from 1 μg total RNA of purified mouse CD4⁺ T cells by a reverse transcriptase SuperScript III and random primers according to the manufacturer’s instructions.
(Invitrogen). Spliced HBZ and GAPDH transcripts were quantified using RT-PCR. The primers used were as follows: HBZ gene: 5'-TAACGATTAGGGGGCCGCTG-3' (sense), 5'-CTGGCATGATGGATGCTGTTT-3' (antisense); GAPDH gene: 5'-GTGGAGA TTGGTGCCCAT TTCAGG-3' (sense) and 5'-AGAGGGGCACCATGCTTTT-3' (antisense). PCR was performed in a PC-808 (Astec) under the following conditions: HBZ 2 minutes at 95°C, followed by 26 cycles of 30 seconds at 95°C, 30 seconds at 59°C and 60 seconds at 72°C; GAPDH: 5 minutes at 95°C, followed by 35 cycles of 30 seconds at 95°C, 30 seconds at 61°C and 30 seconds at 72°C.

Quantitative RT-PCR
To quantify the expression level of HBZ, a TaqMan probe and primers for HBZ were designed. The sequences of primers and probe for HBZ were as follows; HBZ primers: 5'-GAGCAGCTGTTGAGGAGGCAG-3' (sense) and 5'-CCCTCGAGGA TTAATAGCCTGGC-3' (antisense); HBZ probe: 5'-CCCTGTTG CCACTGCCGGAGACCTG-3'. We used the TaqMan Gene expression Assay for 18S rRNA or IL-2 was calculated with the delta delta Ct method.

Retroviral constructs and transduction
For retroviral gene transduction experiments, spliced HBZ cDNA was cloned into a retroviral vector, pMXs-Ig (a gift from T. Kitamura), to generate pMXs-Ig-HBZ. pGCSamiN (kindly provided from M. Onodera) and pGCSamiN-Foxp3 were used as previously described. Transfection of the packaging cell line, Plat-E, was performed as described. For retroviral transduction, CD25-CD4 cells were enriched by a CD4 enrichment kit (BD Pharmingen) and were activated by 0.5 μg/ml anti-CD3 Ab and 50 U/ml IL-2 in the presence of T-cell-depleted and x-irradiated (20 Gy) C57BL/6J splenocytes as APCs in 12 well plates. After 16 hours, activated T cells were transduced with viral supernatant and 4 μg/ml polybrene, and centrifuged at 3,000 rpm for 60 min. Cells were cultured in medium supplemented with 50 μU/ml IL-2. Activation of naive T cells by anti-CD3 antibody influenced expression of these molecules. Therefore, we analyzed their expression after influence by activation was lost [35]. Two days later, Foxp3-mediated CTLA-4 expression was detected by a flow cytometry, and five days later, expression of GITR or CD25 was analyzed. After two days, we stimulated the transduced cells with 50 ng/ml PMA and 1 μg/ml ionomycin in the presence of protein transport inhibitor (BD Pharmingen) for 6 hours, and then analyzed intracellular IL-2 expression using intracellular cytokine staining kits (BD Pharmingen) according to the manufacturer’s instructions.

To elucidate the effect of HBZ on endogenous expression of Treg associated molecules, we transduced HBZ into CD4+Foxp3+ cells purified from mouse splenocytes. Three days after transduction, the expression levels of Treg associated molecules were evaluated by a flow cytometry.

Preparation of splenocytes, flow cytometric analyses, cell sorting, and assays of regulatory T cells
Cell suspensions were prepared from murine spleens by forcing the organs through a nylon mesh, and splenic erythrocytes were eliminated with NH4Cl. Proliferation of murine cells was estimated by 3H-thymidine uptake after 3 days of incubation in RPMI1640 medium supplemented with 10% FCS and 50 μM 2-ME. Flow cytometric analyses and cell sorting were carried out using a FACS CantoII or FACS Aria with Diva Software (BD Pharmingen) and the data was analyzed by FlowJo software (Treestar). For cell surface staining, 10^6 cells were incubated with mAbs for 30 min at 4°C, and then analyzed. For intracellular staining, we used a mouse Foxp3 staining kit according to its protocol (eBioscience). To sort Foxp3+ cells, suspended splenocytes were stained with mAbs for CD4 and GITR, and the CD4+GITR+ fraction was sorted by FACS Aria. Purity of the sorted population was always >90% by re-analysis of Foxp3 staining. For the ex vivo proliferation assay of Foxp3+ cells, carboxyfluorescein diacetate, succinimidyl ester (CFSE)(Molecular Probe) was used according to the manufacturer’s instructions. Foxp3+ T cells (2×10^5/well) were cultured with anti-CD3 antibody (4 μg/ml) in round-bottomed 96-well plates in the presence of x-irradiated splenocytes as antigen presenting cells (APC; 5×10^5/well) for 96 hours. Then, cells were permeabilized, and stained with anti-Foxp3. CFSE dilution was analyzed by flow cytometry. To evaluate the suppressive activity of Foxp3+ T cells sorted from HBZ-Tg or non-Tg mice, Foxp3+ T cells (2×10^5/well) were cultured with CD25-CD4+ cells (2×10^5/well) and APCs (5×10^5/well) from wild-type mice for 72 h in the presence of soluble anti-CD3 (4 μg/ml) or Con A (1 μg/ml), and then [3H] thymidine incorporation was measured.

BrdU staining
In vivo proliferation was measured by BrdU incorporation. BrdU (Nacalai Tesque) was dissolved in PBS (3 μg/ml), and then 200 μl was injected intraperitoneally into HBZ-Tg and non-transgenic mice twice a day for three days as reported previously [53]. BrdU incorporation in CD4+, CD8+, or B220+ splenocytes was detected using FITC BrdU Flow Kits (BD Pharmingen) according to the manufacturer’s instructions. Flow cytometric analyses were performed on a FACS CantoII with Diva Software (BD Pharmingen).

Foxp3 reporter assay
We constructed Foxp3 promoter and enhancer reporter plasmids as the previous report [34]. A murine T-cell line, EL4 cells (1×10^7), were transiently cotransfected by electroporation with the following plasmid DNAs: Foxp3 reporter plasmid, Renilla luciferase control vector (pRL-TK), and HBZ expression vector (pME18SneoHBZ). Cells were cultured with or without TGF-β (2 ng/ml). Firefly and Renilla luciferase activities were measured using the Dual-Luciferase Reporter Assay System (Promega). Relative luciferase activities were calculated as the ratio of firefly and Renilla luciferase activities. The luciferase values are shown as relative values. Values represent means plus standard deviations (error bars) (n = 3).

Histological analyses
The study of clinical samples was approved by the local research ethics committee of the appropriate hospital. Tissue samples were fixed in 10% formalin in phosphate buffer and then embedded in paraffin. Hematoxylin and eosin (H&E) staining was performed according to standard procedures. Images were captured using a Provis AX80 microscope (Olympus) equipped with OLYMPUS DP70 digital camera, and detected using a DP manager system (Olympus).

For analysis of tumors, mice that became immobilized were sacrificed and subjected to autopsy. Tissue samples were surgically removed and fixed in 10% formalin in phosphate buffer and embedded in paraffin. Sections were stained with H&E, for histopathologic examination. After we obtained informed consent, tissue samples from patients who were diagnosed as lymphoma-type ATL were analyzed by immunohistochemical methods to
determine FoxP3 expression. Monoclonal antibodies for CD3ε/500A2; BD PharMingen); B220 (RA3-6B2; BD PharMingen), and Foxp3 (FKJ-16s; ebioscience) were used for immunohistochemistry. We judged CD3εB220ε cases to be T-cell lymphomas since some activated T cells and T cells of the j:p ε/ε mutant mouse expressed B220 [54,55].

**PCR/single stranded conformation polymorphism (SSCP) analysis**

To investigate clonality of lymphoma cells observed in HBZ-Tg mice, lymphoma tissue samples of HBZ-Tg were analyzed for the clonality of T-cell receptor (TCR) γ locus using PCR-SSCP analysis of the TCR γ-gene. Genomic DNA was subjected to PCR amplification using primers for the Vγ2 gene and the Jγ1. The primers were used as follows: Vγ2: 5’-ACCAAGAGATGA-GACTGCAACA-3’ (sense), Jγ1: 5’-GGGTCGTGATCTCTCAAA-TAACCTCCG-3’ (antisense); PCR was performed in a PC-808 (Aste) under the following conditions: 3 minutes at 95°C, followed by 35 cycles of 30 seconds at 95°C, 30 seconds at 55°C and 30 seconds at 72°C. We used EL-4 as a positive control and splenic DNA from young non-Tg or HBZ-Tg mice as negative control. PCR products were run on a 6% polyacrylamide gel and visualized by staining with DNA Silver Staining Kit (GE Healthcare).

**Comunoprecipitation assay and immunoblotting**

Expression vectors for the relevant genes were transiently cotransfected into 293FT cells using the TransIT-LT1 reagent (Mirus Bio). 24 hours later, transfected cells were stimulated with 50 ng/ml PMA and 1 μg/ml ionomycin for another 6 hours. Coimmunoprecipitation assays were performed using the Nuclear Complex Co-IP Kit (Active motif). Briefly, the nuclear extracts of transfected cells were prepared in the presence or absence of ethidium bromide (10 μg/ml). They were precleared with Protein G Sepharose 4 Fast Flow (GE Healthcare), and their supernatants were incubated with anti-myc tag (clone 9E10, Sigma) or anti-Flag tag (Sigma, antibody overnight at 4°C. The immunocomplexes were precipitated with Protein G Sepharose 4 Fast Flow, fractionated in SDS-PAGE, and transferred to PVDF membranes. HBZ-myc-His was detected with horseradish peroxidase (HRP)-conjugated anti-His tag (MBL) antibody. HRP-conjugated anti-Flag tag (Sigma) and anti-α-HA tag (Sigma) antibodies were used to detect Flag-tagged and HA-tagged proteins, respectively. To detect endogenous interaction between HBZ and FoxP3, immunoprecipitation was performed using an ATL cell line, ATL-1 (−), as described above with anti-HBZ antisera and pan-FoxP3 antibody (Abcam). To examine the expression of HBZ in transgenic mice, CD4ε splenocytes from wild type or HBZ-Tg mice were enriched by a mouse CD4ε lymphocyte enrichment set (Pharmingen). Whole cell extracts were prepared with the lysis buffer (50 mM Tris-HCL, PH 7.5, 150 mM NaCl, 1% NP-40), and analyzed by western blotting with anti-HBZ antisera.

**Flow cytometric analysis for HTLV-1 carrier cells**

A previous report demonstrated that Tax expression could not be detected in freshly isolated PBMC from HTLV-1 infected carriers but could be detected when they were cultivated ex vivo for 12 hours [56]. We cultured PBMCs from asymptomatic HTLV-1 carriers for 12 hours and stained with monoclonal antibodies against FoxP3 or Tax (MI-73), and then analyzed by flow cytometry.

**Statistical analysis**

For in vitro experiments, multiple data comparisons were performed using Student’s unpaired t-test. Statistical differences in the incidence of T-cell lymphoma were analyzed using a logrank test.

**Supporting Information**

**Figure S1** Characterization of the transgene. (A) Schematic structure of the transgene. (B) Copy numbers of the transgene in each line were determined by Southern blot analysis. Serially diluted plasmids, used to calculate the copy number, are shown on the left side. Found at: doi:10.1371/journal.ppat.1001274.s001 (0.35 MB TIF)

**Figure S2** Histological analysis of the skin and lung of HBZ-Tg mice. HE staining showed massive infiltration of lymphocytes in HBZ-Tg line 9 and 12, but not in line 2. Immunohistochemical staining revealed that only some of infiltrating lymphocytes were FoxP3 positive. Arrows indicate FoxP3 positive cells. Found at: doi:10.1371/journal.ppat.1001274.s002 (4.46 MB TIF)

**Figure S3** Flow cytometric analysis of TCRβ and TCR γδ expression in the spleen with lymphoma observed in HBZ-Tg mice. Numbers are identical to those of Table 1. Found at: doi:10.1371/journal.ppat.1001274.s003 (0.32 MB TIF)

**Figure S4** PCR/single stranded conformation polymorphism (SSCP) analysis. HBZ-Tg lymphoma tissue samples were analyzed for TCR clonality using PCR-SSCP analysis of the TCR γ-gene. EL-4 are shown as a positive control and splenic DNA from young (less than 6 weeks old) non-Tg or HBZ-Tg mice as a negative control. Lanes 1-5 (#2-3, #9-1, #12-6, #9-3, #12-7) show lymphoma from HBZ-Tg mice respectively (Table 1). Found at: doi:10.1371/journal.ppat.1001274.s004 (1.09 MB TIF)

**Figure S5** Analysis of FoxP3 expression in fresh ATL cells. Immunohistochemical staining for FoxP3 in the lymph nodes of human ATL patients. We used a monoclonal antibody for human FoxP3 (236A/E7; ebioscience). Found at: doi:10.1371/journal.ppat.1001274.s005 (1.89 MB TIF)

**Figure S6** Flow cytometric analysis of thymocyte subsets. Non-Tg or HBZ-Tg thymocytes were stained with anti-CD4 and anti-CD8 antibody, and then analyzed by flow cytometry. Found at: doi:10.1371/journal.ppat.1001274.s006 (0.48 MB TIF)

**Figure S7** Foxp3 expression in spleen, cervical lymph node, or peripheral blood mononuclear cells was determined by flow cytometry. Representative histograms gated on the CD4ε population are shown. Found at: doi:10.1371/journal.ppat.1001274.s007 (0.36 MB TIF)

**Figure S8** HBZ-Tg line 2 also showed an increase in effector memory and regulatory CD4ε T cells. Mouse splenocytes were stained with antibodies for CD4 and CD8 plus CD44 and CD62L (A) or CD25 and Foxp3 (B), and then analyzed by flow cytometry. Representative dot plots gated on the CD4ε population are shown. Found at: doi:10.1371/journal.ppat.1001274.s008 (0.57 MB TIF)

**Figure S9** IL-2 production of CD4ε T cells in HBZ-Tg mice. (A) Mouse splenocytes were stimulated with Leukocyte Activation Cocktail, which contains PMA/Ionomycin and protein transport inhibitor (BD Pharmingen), for 4 hours and then analyzed for intracellular IL-2 gated on the CD4ε cells by flow cytometry. Representative results of more than three independent experiments are shown. (B) The percentage of IL-2ε cells among Foxp3ε cells is shown. The results shown are the mean ± SD of triplicate experiments. Found at: doi:10.1371/journal.ppat.1001274.s009 (0.26 MB TIF)
Figure S10  Flow cytometric analyses of tax-Tg mice. Non-Tg or tax-Tg splenocytes were stained with the indicated antibodies, and analyzed by flow cytometry. Representative dot plots gated on the CD4 + population are shown.

Figure S11  The effect of HBZ on Foxp3/AML-1 complex. (A) 293FT-cells were co-transfected with vectors expressing the indicated proteins, lysed, and subjected to immunoprecipitation. (B) Jurkat cells were co-transfected with expression vectors for the indicated proteins and IL-2 promoter-luc constructs. The results shown are relative values of firefly luciferase normalized to Renilla luciferase and expressed as means ± SD. The experiments were repeated three times with similar results.

Figure S12  Characterization of the interaction between HBZ and NFAT. To investigate the region responsible for each interaction, we performed immunoprecipitation experiments with NFATC2 and deletion mutants of HBZ. Asterisk shows the region responsible for the molecular interaction.

Figure S13  The percentages of HTLV-1+ T cells in CD4+/FoxP3− and CD4+/FoxP3+ subpopulations of asymptomatic HTLV-1 carriers. It has been reported that ex vivo culture induces the reactivation of viral antigen in HTLV-1 infected cells. We cultured freshly isolated PBMC from two asymptomatic HTLV-1 carriers for 18 hours, and then stained intracellular Tax as a viral antigen to detect the presence of HTLV-1 by using a monoclonal antibody of Tax (MI-73).

Table S1  (A) Summary of BrdU incorporation in vivo. Data shown are percentage of BrdU positive cells of three different non-Tg or HBZ−/− mice. (B) MFI of Treg associated molecules (CTLA-4, GITR, CD103, or CCR4) in non-Tg or HBZ−/− mice (12 mice) are shown as mean ± SD (n = 3), of three mice.

Acknowledgments
We thank A. Koito for H/M/T-CD4 vector; T. Kitamura for the pMXs-Ig vector and Plat-E cell; M. Onodera for the pGCSamIN vector; and J. Tanabe and A. Kamamoto for technical assistance, and Aaron Couotts and Kate Hayes-Ozello for editorial comments.
