Kyoto University
Equivariant cohomology determines hypertoric manifold

Dep. of Mathematical Sciences KAIST  黒木 慎太郎 (Shintarô Kuroki)
Korean Advanced Institute of Science and Technology (KAIST)

ABSTRACT. In this article, we prove that if two equivariant cohomologies of hypertoric manifolds are isomorphic then these hypertoric manifolds are equivariantly diffeomorphic.

1. Introduction

In [BD00], Bielowsky and Dancer introduce the hypertoric variety\(^1\) as the hyperKähler analogue of symplectic toric variety. The hypertoric variety is defined by the hyperKähler quotient of the standard torus action on \(\mathbb{H}^n\) where \(\mathbb{H}\) is the quaternionic space, and belongs to the class \((M^{4n}, T^n)\), i.e., 4n-dimensional space with n-dimensional torus action. This notion is different from the toric variety which belongs to the class \((M^{2n}, T^n)\); however, there are some similar properties in toric and hypertoric varieties. For example, the hypertoric variety is determined by the combinatorial data of the hyperplane arrangement as well as the symplectic toric varieties are determined by the combinatorial data of polytopes. In the paper [M08], Masuda proved that the equivariant cohomology of the non-singular toric variety (toric manifold) determines the polytope; therefore, the equivariant cohomology also determines the equivariant types of toric manifolds. The aim of this article is to prove the hypertoric analogue of the Masuda's theorem. The following theorem for two hypertoric manifolds \((M, T)\) and \((M', T)\) are the main theorem of this article.

**Theorem 1.1.** If \(H_T^*(M; \mathbb{Z}) \cong H_T^*(M'; \mathbb{Z})\), i.e., they are isomorphic up to \(H^*(BT)\)-algebra, then \((M, T) \equiv (M', T)\), i.e., they are \(T\)-equivariantly isometric.

By Theorem 1.1, we can easily show the following corollary.

**Corollary 1.2.** If \(H_T^*(M; \mathbb{Z}) \cong H_T^*(M'; \mathbb{Z})\), then \((M, T) \cong (M', T)\), i.e., they are \(T\)-equivariantly diffeomorphic.

The organization of this article is as follows. In Section 2, we recall the definition of the hypertoric manifolds and their basic properties. In Section 3, we give an outline of the proof of the main theorem. In the final section (Section 4), we point out the Nishimura's suggestion and give the problem for the case of the (hyper)toric orbifold.

2. The hypertoric variety and hyperplane arrangement

In this section, we recall the definition of the hypertoric variety and how to define hyperplane arrangement from the hypertoric variety (see [BD00], [Ko08] or [P08] for detail). We assume throughout this article that \(\mathbb{R}\) is the real space, \(\mathbb{C}\) is the complex space and \(\mathbb{H}\) is the quaternionic space, i.e., \(\mathbb{H} \cong \mathbb{R}^4\) as the \(\mathbb{R}\)-vector space and basis \(i, j, k\) except 1 satisfy the following multiplicative relations:

\[
ijk = i^2 = j^2 = k^2 = -1.
\]

\(^1\)The former terminology was toric hyperKähler.
2.1. The definition of the hypertoric variety. Assume $\mathbb{H}^m$ is the $m$-dimensional quaternionic vector space with the left $\mathbb{H}$-scator product. The $m$-dimensional torus $T^m$ acts on $\mathbb{H}^m$ via the left scalar product, i.e., we can denote it explicitly as follows:

$$
\mathbb{H}^m \longrightarrow \mathbb{H}^m
$$

$$
z + jw \quad \mapsto \quad tz + j^{-1}w
$$

for $z, w \in \mathbb{C}^m$ and $t \in T^m$. By using this torus action on $\mathbb{H}^m \cong \mathbb{C}^m \oplus \mathbb{C}^m$, we can regard $\mathbb{H}^m$ as $T^* \mathbb{C}^m$, i.e., the cotangent bundle of $\mathbb{C}^m$; or $\mathbb{C}^m \oplus \overline{\mathbb{C}^m}$, where $\overline{\mathbb{C}^m}$ is the orientation reversing space of $\mathbb{C}^m$.

Moreover, the holomorphic two form $\omega_C = \omega_J + \sqrt{-1} \omega_K$ gives the holomorphic symplectic structure on $\mathbb{H}^m$ if we regard the complex structure on $\mathbb{H}^m$ as $I$. Then the above $T^m$-action on $\mathbb{H}^m$ preserves symplectic structures $\omega_I = \omega_R$ and $\omega_C$, and determines the hyperKähler moment map

$$
\mu_R \oplus \mu_C : \mathbb{H}^m \longrightarrow (t^m)^* \oplus (t_C^m)^*
$$

such that

$$
\mu_R(z, w) = \frac{1}{2} \sum_{i=1}^{m} (|z_i|^2 - |w_i|^2) \partial_i
$$

and

$$
\mu_C(z, w) = 2 \sqrt{-1} \sum_{i=1}^{m} z_i w_i \partial_i,
$$

where $z = (z_1, \ldots, z_m) \in \mathbb{C}^m$ and $w = (w_1, \ldots, w_m) \in \overline{\mathbb{C}^m}$ and $\partial_i (i = 1, \ldots, m)$ is the basis in $(t^m)^*$ and $(t_C^m)^*$.

Put the subtorus $K \subset T^m$. Then there is the following sequence:

$$
K \longrightarrow t^m \quad \longrightarrow \quad T^m / K \cong T^n,
$$

where $\iota$ is the natural embedding homomorphism, $\rho$ is the projection to the cokernel of $\iota$ and $n = m - \dim K$. This sequence induces the following exact sequence of Lie algebras:

$$
\{0\} \longrightarrow \mathfrak{k} \quad \longrightarrow \quad t^m \quad \longrightarrow \quad \{t\}.
$$

By taking the dual of this sequence, we have the following exact sequence of the dual Lie algebras:

$$(2.1) \quad \{0\} \longrightarrow (t^n)^* \quad \longrightarrow \quad (t^m)^* \quad \longrightarrow \quad \{t^*\}.
$$

By using $\iota^*$ and its complexification $\iota_C^*$, we can define the hyperKähler moment map of $K$-action on $\mathbb{H}^m$ as follows:

$$
\mu_{HK} : \mathbb{H}^m \longrightarrow (t^m)^* \oplus (t_C^m)^* \quad \longrightarrow \quad t^* \oplus t_C^*.
$$

By the definition of $\mu_{HK}$, we may take $(\alpha, 0) \in \mathfrak{k}^* \oplus \mathfrak{t}_C^*$ for $\alpha \neq 0$ as the regular value of $\mu_{HK}$. Hence, its inverse image $\mu_{HK}^{-1}(\alpha, 0)$ has the almost free $K$-action because $\mu_{HK}$ is the $K$-equivariant map and $K$ acts on $\mathfrak{t}^* \oplus \mathfrak{t}_C^*$ trivially. Therefore, if we take its quotient space $\mu_{HK}^{-1}(\alpha, 0)/K$ then this becomes an orbifold with dimension $4n$. Moreover, $\mu_{HK}^{-1}(\alpha, 0)/K$ has the $T^m/K = T^n$ action. We call $\mu_{HK}^{-1}(\alpha, 0)/K$ a hypertoric variety. If hypertoric variety is non-singular, then we call it a hypertoric manifold. The following proposition gives the criterion of the hypertoric manifold (see [Ko00, Proposition 2.2]).

**Proposition 2.1.** The following two statements are equivalent.

1. The action of $K$ on $\mu_{HK}^{-1}(\alpha, 0)$ is free, i.e., $\mu_{HK}^{-1}(\alpha, 0)/K$ is a manifold.
EQUIVARIANT COHOMOLOGY DETERMINES HYPERTORIC MANIFOLD

(2) For any $J \subset \{1, \ldots , m\}$ such that $\{\iota^{*}u_{j} \mid j \in J\}$ forms a basis of $\mathfrak{k}^{*}$,

$$t_{Z}^{m} = \mathfrak{k}_{Z} \oplus \sum_{j \in J^{c}} \mathbb{Z}\partial_{j}$$

as a $\mathbb{Z}$-module,

where $\mathfrak{k} \subset \mathfrak{t}$ via $\iota_{*}$, and $\mathfrak{k}_{Z}$ and $t_{Z}$ are their lattice subgroups.

Moreover, we have the following proposition (see [P04, Lemma 3.4]).

**Proposition 2.2.** Let $\mu_{HK}^{-1}(\alpha, 0)/K$ and $\mu_{HK}^{-1}(\alpha', 0)/K$ be hypertoric manifolds defined by $K \subset T^{m}$ and two non-zero elements $\alpha$, $\alpha' \in \mathfrak{k}^{*}$. Then

$$\mu_{HK}^{-1}(\alpha, 0)/K \cong \mu_{HK}^{-1}(\alpha', 0)/K$$

as $T^{m}$-equivariant diffeomorphism.

The following example is one of the standard examples in hypertoric manifolds.

**Example 2.3.** Let $\Delta$ be the diagonal subgroup in $T^{n+1}$. Then the hypertoric variety induced by $\Delta$ is equivariantly diffeomorphic to $T^{*}\mathbb{C}P^{n}$ with the induced $T^{n}$ action from the $T^{m}$-action on $\mathbb{C}P^{n}$.

**2.2. The hyperplane arrangement.** In this subsection, we introduce the hyperplane arrangement associated with hypertoric varieties.

First, we give the flow chart to define the hypertoric variety.

1. Take a subgroup $K \subset T^{m}$.
2. Take a non-zero element $\alpha \in \mathfrak{k}^{*}$.
3. Take the hyperKähler quotient $\mu_{HK}^{-1}(\alpha, 0)/K$.

In the first step of this flow chart, we have the exact sequence (2.1):

$$\{0\} \longrightarrow (t^{n})^{*} \xrightarrow{\rho^{*}} (t^{m})^{*} \xrightarrow{\iota^{*}} t^{*} \longrightarrow \{0\}.$$

By the exactness of the above sequence, we can take the lift of $\alpha$ (in the second step of the above flow chart) as follows:

$$\begin{array}{ccc}
(t^{m})^{*} & \xrightarrow{\iota^{*}} & \mathfrak{k}^{*} \\
\downarrow & & \downarrow \\
\alpha & \longrightarrow & \iota^{*}(\alpha).
\end{array}$$

i.e., $\iota^{*}(\alpha) = \alpha$. Then we may define $m$ hyperplanes in $(t^{n})^{*}$ as follows:

$$H_{i} = \{x \in (t^{n})^{*} \mid \langle \rho^{*}(x) + \alpha, e_{i} \rangle = 0\}$$

where $e_{i}$ ($i = 1, \ldots , m$) is the basis of $t^{m} \simeq \mathbb{R}^{m}$. We call

$$\mathcal{H} = \{H_{1}, \ldots , H_{m}\}$$

a hyperplane arrangement of $\mu_{HK}^{-1}(\alpha, 0)/K$. Note that the combinatorial structure of $\mathcal{H}$ does not depend on the choice of the lift $\alpha$; in fact, only the parallel translations of $H_{i}$'s occur by changing lifts of $\alpha$.

Now we show a hyperplane arrangement of $T^{*}\mathbb{C}P^{n}$.

**Example 2.4.** Let $T^{*}\mathbb{C}P^{n}$ be the cotangent bundle over $\mathbb{C}P^{n}$. Due to Example 2.3, the subgroup $\Delta \simeq S^{1}$ defines $T^{*}\mathbb{C}P^{n}$. Therefore, we have the following exact sequence:

$$\begin{array}{ccc}
(t^{n})^{*} & \xrightarrow{\iota^{*}} & (t^{n+1})^{*} \\
\epsilon^{*} & \longrightarrow & \mathbb{R}
\end{array}$$

where $\mathbb{R}$ is the dual of Lie algebra of $\Delta$. Because $\Delta$ is the diagonal subgroup, the representation $\iota^{*}$ is written as

$$\iota^{*}(x_{1}, \ldots , x_{n+1}) = x_{1} + \cdots + x_{n+1} \in \mathbb{R}.$$
EQUIVARIANT COHOMOLOGY DETERMINES HYPERTORIC MANIFOLD

Because of the exactness, we may define the representation $\rho^*$ as follows:

$$\rho^*(t_1, \ldots, t_n) = (t_1, \ldots, t_n, -t_1 - \cdots - t_n) \in (t^{n+1})^*$$

Take $\alpha = n + 1 \in \mathbb{R}$. Then we can take its lift $\tilde{\alpha}$ as $\tilde{\alpha} = (1, \ldots, 1)$. By the definition of hyperplane arrangement of $\mu_{HK}^{-1}(\alpha, 0)/\Delta$, we have the following hyperplanes:

$$H_1 = \{(t_1, \ldots, t_n) \in (t^n)^* | t_1 = -1\};$$
$$\vdots$$
$$H_n = \{(t_1, \ldots, t_n) \in (t^n)^* | t_n = -1\};$$
$$H_{n+1} = \{(t_1, \ldots, t_n) \in (t^n)^* | t_1 + \cdots + t_n = 1\}.$$

The following Figure 1 shows the case $n = 2$.

![Figure 1. A hyperplane arrangement of $T^*\mathbb{C}P(2)$]

By using the combinatorial data of $\mathcal{H}$, we can describe the ring structure of the equivariant cohomology (see Section 3.1) of hypertoric manifolds.

**Theorem 2.5 (Konno [Ko99]).** Let $(M, T)$ be the hypertoric manifold and $\mathcal{H} = \{H_1, \ldots, H_m\}$ a hyperplane arrangement of $M$. Then its equivariant cohomology $H^*_T(M)$ is denoted as follows:

$$H^*_T(M; \mathbb{Z}) \simeq \mathbb{Z}[\tau_1, \ldots, \tau_m]/\mathcal{I}$$

where $\deg \tau_i = 2$ and $\mathcal{I}$ is the ideal in the polynomial ring $\mathbb{Z}[\tau_1, \ldots, \tau_m]$ generated by

$$\prod_{i \in I} \tau_i$$

for $\bigcap_{i \in I} H_i = \emptyset$.

Here, $I$ is the subset of $[m] = \{1, \ldots, m\}$.

The above generator $\tau_i$ ($i = 1, \ldots, m$) corresponds with the line bundle of $M$ which will be described as follows. Let $p_i : T^m \to T_i \simeq S^1$ be the natural projection to the $i$-th coordinate. Then we can define the $\mathbb{H}$-line bundle over $M = \mu_{HK}^{-1}(\alpha, 0)/K$ as follows:

$$\mu_{HK}^{-1}(\alpha, 0) \times_K \mathbb{H}_{p_i},$$

where $\mathbb{H}_{p_i}$ is the vector space which is isomorphic to $\mathbb{H}$ with the $K$-action via $K \subset T^m \overset{p_i}{\longrightarrow} S^1$, and $\mu_{HK}^{-1}(\alpha, 0) \times_K \mathbb{H}_{p_i}$ is the orbit space $(\mu_{HK}^{-1}(\alpha, 0) \times \mathbb{H}_{p_i})/K$. Then this bundle splits into the following bundle:

$$\mu_{HK}^{-1}(\alpha, 0) \times_K \mathbb{H}_{p_i} \equiv \mu_{HK}^{-1}(\alpha, 0) \times_K (\mathbb{C}_{p_i} \oplus \overline{\mathbb{C}_{p_i}}).$$

Put $\mu_{HK}^{-1}(\alpha, 0) \times_K \mathbb{C}_{p_i} = L_i$. The 1st chern class of $L_i$ is the generator $\tau_i$, i.e.,

$$c_1(L_i) = \tau_i.$$
Remark 2.6. For the toric manifold \((M^{2n}, T^n)\) case, the \(S^1\)-invariant submanifold (characteristic submanifold) becomes a manifold with dimension \(2n-2\); and the generators of \(H^*_T(M^{2n})\) are expressed by taking the Poincaré dual of such invariant submanifold. On the other hand, for the hypertoric manifold \((M^{4n}, T^n)\) case, such invariant submanifold becomes a manifold with dimension \(4n - 4\). Therefore, its Poincaré dual lives in \(H^*_T(M)\). And this Poincaré dual becomes \(c_2(L_i \oplus \overline{L_i}) = -\tau_i^2\) for \(i = 1, \ldots, m\). This property of hypertoric manifolds is one of the different properties with toric manifolds.

Example 2.7. For the cotangent bundle \(T^*CP^n\) over \(CP^n\) (see Example 2.3), by using Example 2.4 and Theorem 2.5, we have the following formula:

\[ H^*_T(T^*CP^n; \mathbb{Z}) \cong \mathbb{Z}[\tau_1, \ldots, \tau_{n+1}]/(\tau_1 \cdots \tau_{n+1}) \]

for the generators \(\tau_i \in H^*_T(T^*CP^n; \mathbb{Z})\).

3. Outline of the proof of the main theorem

Throughout this section, we assume that \((M, T)\) is a hypertoric manifold. The purpose of this section is to give the outline of the proof of Theorem 1.1 (see [Ku2] for detail).

3.1. Equivariant cohomology. In order to prove Theorem 1.1, first we recall the equivariant cohomology. Before we state its definition, we prepare some notations.

The symbol \(ET\) represents a universal space of \(T\), i.e., \(ET\) satisfies the following two properties:

1. \(ET\) is contractible;
2. \(T\) acts on \(ET\) freely,

and \(BT\) represents its classifying space, i.e., \(BT = ET/T\). Then the product space \(ET \times M\) has the diagonal \(T\)-action, and we denote its orbit space \((ET \times M)/T\) by \(ET \times_T M\). Because \(T\) acts freely on the \(ET\) factor in \(ET \times M\), there is the following fibration:

\[ M \xrightarrow{j} ET \times_T M \xrightarrow{\pi} BT. \]

We call the ordinary cohomology \(H^*(ET \times_T M)\) the equivariant cohomology of \((M, T)\) and denote it by \(H^*_T(M)\). By using the fibration (3.1), we have the following homomorphism:

\[ \pi^*: H^*(BT) \rightarrow H^*_T(M). \]

Thus, we can regard \(H^*_T(M)\) as not only the ring but also the \(H^*(BT)\)-algebra via \(\pi^*\). Note that \(H^*(BT; \mathcal{R})\) is isomorphic to the polynomial ring (see [MT91]), i.e.,

\[ H^*(BT; \mathcal{R}) \cong \mathcal{R}[x_1, \ldots, x_n] \]

for all coefficient ring \(\mathcal{R}\), where \(\dim T = n\) and \(\deg x_i = 2 (i = 1, \ldots, n)\).

Due to the Konno's theorem (Theorem 2.5), we have the following exact sequence:

\[ \{0\} \rightarrow H^2(BT; \mathbb{Z}) \xrightarrow{\pi^*} H^2_T(M; \mathbb{Z}) \xrightarrow{j^*} H^2(M; \mathbb{Z}) \rightarrow \{0\}. \]

Moreover, by using the similar argument in [M08, Proposition 2.2], the representation \(\pi^*\) in (3.2) can be expressed as the following proposition.

Proposition 3.1. To each \(i \in [m]\), there is a unique element \(v_i \in H_2(BT; \mathbb{Z})\) such that

\[ \pi^*(x) = \sum_{i=1}^{m} \langle x, v_i \rangle \tau_i \]

for any \(x \in H^2(BT; \mathbb{Z})\), where \(\langle , \rangle\) is the pairing of the cohomology and homology.

By taking each tensor product with \(\mathbb{R}\) in the sequence (3.2), the sequence (3.2) induces the following exact sequence:

\[ \{0\} \rightarrow H^2(BT^n; \mathbb{R}) \xrightarrow{\pi^*_n} H^2_T(M; \mathbb{R}) \xrightarrow{j^*_n} H^2(M; \mathbb{R}) \rightarrow \{0\}. \]
Because the above sequence (3.3) is the extension of the sequence (3.2), the representation $\pi^*_R$ is also expressed as

$$\pi^*_R(x) = \sum_{i=1}^m \langle x, v_i \rangle \tau_i$$

for a unique element $v_i \in H_2(BT; \mathbb{Z})$.

The key point of the proof is to construct the hyperplane arrangement in the equivariant cohomology $H^*_T(M; \mathbb{R})$. We will describe it in the next subsection.

### 3.2. Hyperplane arrangement in the equivariant cohomology

The goal of this section is to construct the hyperplane arrangement in $H^2(BT; \mathbb{R})$ by using the sequence (3.3). In order to construct it, we will prove the following key lemma.

**Lemma 3.2.** The following diagram is commutative:

$$
\begin{array}{ccccccccc}
0 & \rightarrow & (t^n)^* & \rightarrow & (t^n)^* & \rightarrow & t^* & \rightarrow & 0 \\
\downarrow J_{t}^* & & \downarrow J_{t}^* & & \downarrow J_{t}^* & & \downarrow J_{t}^* & & \downarrow J_{t}^* & & \downarrow J_{t}^* & & 0 \\
0 & \rightarrow & H^2(BT^n; \mathbb{R}) & \rightarrow & H^2_T(M; \mathbb{R}) & \rightarrow & J_{t}^* & \rightarrow & H^2(M; \mathbb{R}) & \rightarrow & 0 \\
\end{array}
$$

Here, the isomorphism $J_{t}^*$ is defined by $H_2(BT; \mathbb{Z}) \simeq \text{Hom}(S^1, T^n) \simeq t^n_2$, the isomorphism $J_{t}^*_m$ is defined by $e_i^* \mapsto \tau_i$ for $i = 1, \ldots, m$, and $J_{t}^*_K$ is induced homomorphism from $J_{t}^*_m$ and $J_{t}^*_n$. Now we may start to prove this lemma.

**Outline of the proof of Lemma 3.2.** With the method similarly to show the equation (3.4), we have the following equations:

$$\rho^*(u) = \sum_{i=1}^m \langle u, \tilde{v}_i \rangle e_i,$$

for some unique element $\tilde{v}_i \in t^n_2$ for $i = 1, \ldots, m$. Because of the equation (3.4), we have

$$\pi^*_R(x) = \sum_{i=1}^m \langle x, v_i \rangle \tau_i.$$

Therefore, in order to have the commutativity of the first diagram, we need to prove that

$$
\begin{array}{ccccc}
t^n_2 & \stackrel{(J_n)_*}{\rightarrow} & H_2(BT; \mathbb{Z}) \\
\downarrow \psi & & \downarrow \psi \\
\tilde{v}_i & \mapsto & v_i \\
\end{array}
$$

for $i = 1, \ldots, m$. This fact is known by using the following fact: the image of two corresponding elements $f_{\tilde{v}_i}, f_{v_i} \in \text{Hom}(S^1, T^n)$ determine the same isotropy subgroup of characteristic submanifold $M_i$ for $i = 1, \ldots, m$. Therefore, $(J_n)_*: \tilde{v}_i \mapsto \pm v_i$. If $(J_n)_*(\tilde{v}_i) = -v_i$, then we change $\tau_i$ to $-\tau_i$. Then we have $(J_n)_*(\tilde{v}_i) = v_i$ and the commutativity of the first diagram.

For the second diagram, the isomorphism $J_{t}^*_K$ is induced by the first diagram. Hence, the second diagram is commute. \(\Box\)

Now we may construct the hyperplane arrangement in $H^2(BT; \mathbb{R})$. First we recall the construction of the hyperplane arrangement in $(t^n)^*$. Because of the definition of the hypertoric manifolds, there is some non-zero element $\alpha \in t^n_*$ such that $M = \mu^{-1}_H(\alpha, 0)/K$. According to the construction of the hyperplane in $(t^n)^*$, we can take its lift $\tilde{\alpha} \in (t^n)^*$ such that this gives the hyperplane arrangement $\mathcal{H}_{\tilde{\alpha}}$ in $(t^n)^*$.

Because $J_{t}^*_K$ is isomorphism, we can take the non-zero element $\beta = J_{t}^*_K(\alpha) \in H^2(M)$. By taking $J_{t}^*_n(\tilde{\alpha}) = \tilde{\beta}$, we have $J_{t}^*_n(J_{t}^*_K(\alpha)) = \beta$. With the method similar to construct $\mathcal{H}_{\tilde{\alpha}}$, we have the hyperplane $\mathcal{H}_{\tilde{\beta}}$ in $H^2(BT; \mathbb{R})$. Then we have the following lemma.

**Lemma 3.3.** The isomorphism $J_{t}^*_n: (t^n)^* \rightarrow H^2(BT; \mathbb{R})$ preserves $\mathcal{H}_{\tilde{\alpha}}$ to $\mathcal{H}_{\tilde{\beta}}$. 
Outline of proof. A hyperplane $H_i \in \mathcal{H}_{\tilde{\beta}}$ is written as follows:

$$H_i = \{ u \in (t^i)^* \mid \langle \rho^*(u) + \tilde{\alpha}, e_i \rangle = 0 \}.$$ 

This hyperplane goes to the following set by using $J_n^*$. 

$$H'_i = \{ x = J_n^*(u) \in H^2(BT; \mathbb{R}) \mid \langle \rho^*(u) + \tilde{\alpha}, e_i \rangle = 0 \}.$$ 

Then we have 

$$\langle \rho^*(u) + \tilde{\alpha}, e_i \rangle = 0$$

$$\langle \rho^*(u) + \tilde{\alpha}, (J_m)_*(\mu_i) \rangle = 0$$

$$\langle J_n^* \circ \rho^*(u) + J_n^*(\tilde{\alpha}), \mu_i \rangle = 0$$

$$\langle \pi_r^* \circ J_n^*(u) + \tilde{\beta}, \mu_i \rangle = 0$$

where $\mu_i \in H^2_T(M; \mathbb{R})$ is the element which corresponds to $\tau_i \in H^2_T(M; \mathbb{R})$. Therefore, $H'_i$ is the element in $\mathcal{H}_{\tilde{\beta}}$.

This means that we show the following theorem.

**Theorem 3.4.** Let $(M, T)$ be the hypertoric manifold and $\mathcal{H}$ be a hyperplane arrangement of $M$. Then we can define the hyperplane arrangement $\mathcal{H}'$ in $H^2(BT; \mathbb{R})$ such that $J^*_n : (t^i)^* \to H^2(BT; \mathbb{R})$ preserves $\mathcal{H}$ to $\mathcal{H}'$.

3.3. Outline of the proof of the main theorem. In this section, we prove Theorem 1.1. Let $(M, T)$ and $(M', T)$ be hypertoric manifolds. Assume $H^*_T(M; \mathbb{Z}) \cong H^*_T(M'; \mathbb{Z})$ as the $H^*(BT; \mathbb{Z})$-algebra, that is, there is the ring isomorphism $f_T : H^*_T(M; \mathbb{Z}) \to H^*_T(M'; \mathbb{Z})$ such that 

$$f_T(rx) = rf_T(x)$$

for all $x \in H^*_T(M; \mathbb{Z})$ and $r \in H^*(BT; \mathbb{Z})$. Note that we denote the induced ring isomorphism $H^*(M; \mathbb{Z}) \to H^*(M'; \mathbb{Z})$ by $f$. Then we have the following commutative diagrams:

$$\begin{array}{cccc}
0 & \longrightarrow & H^2(BT; \mathbb{R}) & \xrightarrow{\pi_r^*} & H^2_T(M; \mathbb{R}) & \xrightarrow{J_n^*} & H^2(M; \mathbb{R}) & \longrightarrow & 0 \\
0 & \longrightarrow & H^2(BT'; \mathbb{R}) & \xrightarrow{\pi_r^*} & H^2_T(M'; \mathbb{R}) & \xrightarrow{J_n^*} & H^2(M'; \mathbb{R}) & \longrightarrow & 0
\end{array}$$

Let $\beta \in H^2(M; \mathbb{R})$ be a non-zero element and $\tilde{\beta} \in H^2_T(M; \mathbb{R})$ be its lift. The goal of this section is to show that $\mathcal{H}_{\tilde{\beta}}$ and $\mathcal{H}_{f_T(\tilde{\beta})}$ are precisely same hyperplane arrangement. In order to show this fact, it is sufficient to prove the following proposition.

**Proposition 3.5.** If $f_T$ is an $H^*(BT; \mathbb{Z})$-algebra isomorphism between $H^*_T(M; \mathbb{Z})$ to $H^*_T(M'; \mathbb{Z})$, then $f_T$ preserves $\{ \tau_1, \ldots, \tau_m \}$ to $\{ \tau'_1, \ldots, \tau'_m \}$ up to signs. In other words, $\mathcal{H}_{\tilde{\beta}}$ and $\mathcal{H}_{f_T(\tilde{\beta})}$ are precisely same hyperplane arrangement up to coorientations of hyperplanes.

Let $M^T$ be the set of $T$-fixed points in $M$. As is well known, it consists of finitely many points. For $\xi \in H^2_T(M; \mathbb{Z})$, we denote its restriction to $p \in M^T$ by $\xi|_p$ and define 

$$Z(\xi) := \{ p \in M^T \mid \xi|_p = 0 \}.$$

**Lemma 3.6.** Express $\xi = \sum_{i=1}^m a_i \tau_i$ with integers $a_i$. If $a_i \neq 0$ for some $i$, then $Z(\xi) \subset Z(\tau_i)$. Moreover, if $a_i \neq 0$ and $a_j \neq 0$ for some different $i$ and $j$, then $Z(\xi) \subset Z(\tau_i) \cap Z(\tau_j)$.

**Proof.** Let $p \in M^T$. Recall $L_i = \mu_K(\alpha, 0) \times_K \mathbb{C}p_i$ (see Section 2). This line bundle $L_i$ satisfies that $L_i \oplus L_i|_{M_i}$ is the normal bundle of $M_i$ and $L_i|_{M \setminus M_i}$ is the trivial bundle by the definition, where $M_i$ is the characteristic submanifold. Since $\tau_i = c_1(L_i)$, we have that $\tau_i|_p = 0$ if $p \notin M_i$. Moreover, if $p \in M_i$, then 

$$\tau_i|_p = c_1(L_i|_p) \in H^2_T(p; \mathbb{Z}) = H^2(BT; \mathbb{Z}).$$

This implies that 

$$\tau_i|_p = 0 \quad \text{if and only if} \quad p \notin M_i.$$
and that there are exactly \( n \) number of \( M_i \)'s containing \( p \) and \( \{ \tau_i \mid p \in M_i \} \) forms a basis of \( H^2(BT;\mathbb{Z}) \).

Suppose \( p \in Z(\xi) \). Then \( 0 = \xi|_p = \sum_{i=1}^m a_i \tau_i|_p \) and it follows from the observation above that \( \tau_i|_p = 0 \) if \( a_i \neq 0 \). Therefore, we have \( Z(\xi) \subset Z(\tau_i) \) (former statement).

If both \( a_i \) and \( a_j \) are non-zero, then \( Z(\xi) \subset Z(\tau_i) \cap Z(\tau_j) \) by the former statement in the lemma. Therefore, it suffices to prove that \( Z(\tau_i) \cap Z(\tau_j) \) is properly contained in \( Z(\tau_i) \). Suppose that \( Z(\tau_i) \cap Z(\tau_j) = Z(\tau_i) \). Then \( Z(\tau_j) \supset Z(\tau_i) \), so \( M_j^T \subset M_i^T \) by (3.6). This implies that \( M_j = M_i \), a contradiction. \( \square \)

Let \( S = H^*(BT;\mathbb{Z}) \setminus \{0\} \) and let \( S^{-1}H^*_T(M;\mathbb{Z}) \) denote the localized ring of \( H^*_T(M;\mathbb{Z}) \) by \( S \), i.e.,

\[
S^{-1}H^*_T(M;\mathbb{Z}) = \left\{ \frac{r}{s} \mid r \in H^*_T(M;\mathbb{Z}), \ s \in S \right\}/ \sim
\]

where

\[
\frac{r_1}{s_1} \sim \frac{r_2}{s_2} \iff (r_1s_2 - r_2s_1)t = 0 \quad \text{for some} \quad t \in S.
\]

Since \( H^{odd}(M;\mathbb{Z}) = 0 \), \( H^*_T(M;\mathbb{Z}) \) is free as a module over \( H^*(BT;\mathbb{Z}) \). Hence, the natural map

\[
H^*_T(M;\mathbb{Z}) \to S^{-1}H^*_T(M;\mathbb{Z}) \cong S^{-1}H^*_T(M^T;\mathbb{Z}) = \bigoplus_{p \in M^T} S^{-1}H^*_T(p;\mathbb{Z})
\]

is injective, where the above isomorphism is induced from the inclusion map from \( M^T \) to \( M \) and is a consequence of the Localization Theorem in equivariant cohomology ([H75, p.40]). The annihilator

\[
\text{Ann}(\xi) := \{ \eta \in S^{-1}H^*_T(M;\mathbb{Z}) \mid \eta \xi = 0 \} \subset \bigoplus_{p \in M^T} S^{-1}H^*_T(p;\mathbb{Z})
\]

of \( \xi \) is nothing but the sum of \( S^{-1}H^*_T(p;\mathbb{Z}) \) over \( p \) with \( \xi|_p = 0 \), because if \( \xi|_p \neq 0 \) then we have \( \eta|_p = 0 \). Therefore, it is a free \( S^{-1}H^*(BT;\mathbb{Z}) \) module of rank \( |Z(\xi)| \). Since \( \text{Ann}(\xi) \) is defined using the algebra structure of \( H^*_T(M;\mathbb{Z}) \), \( |Z(\xi)| \) is an invariant of \( \xi \) depending only on the algebra structure of \( H^*_T(M;\mathbb{Z}) \). We note that \( |Z(\xi)| \) is invariant under an algebra isomorphism. We call \( |Z(\xi)| \) the zero-length of \( \xi \).

Now we may start to prove Proposition 3.5.

**Proof of Proposition 3.5.** Let \( T_1 \) be the set of \( \tau_i \)'s in \( H^2_T(M) \) with largest zero-length, and let \( T_2 \) be the set of \( \tau_i \)'s in \( H^2_T(M) \) with second largest zero-length, and so on. Similarly we define \( T'_1, T'_2 \) and so on for \( \tau_i \)'s in \( H^2_T(M') \).

Let \( m_k \) (resp. \( m'_k \)) be the zero-length of elements in \( T_k \) (resp. \( T'_k \)). Since both \( f_T \) and \( f_T^{-1} \) preserve zero-length and are isomorphisms, \( m_1 = m'_1 \) and \( f_T \) maps \( T_1 \) to \( T'_1 \) bijectively up to sign by Lemma 3.6. Take an element \( \tau_1 \) from \( T_2 \). Since \( T_1 \) and \( T'_1 \) are preserved under \( f_T \) and \( f_T^{-1} \), \( f_T(\tau_1) \) is not a linear combination of elements in \( T'_1 \). This together with Lemma 3.6 means that \( m_2 \leq m'_2 \). The same argument for \( f_T^{-1} \) instead of \( f_T \) shows that \( m'_2 \leq m_2 \), so that \( m_2 = m'_2 \).

Again, this together with Lemma 3.6 implies that \( f \) maps \( T_2 \) to \( T'_2 \) bijectively up to sign. The lemma follows by repeating this argument. \( \square \)

Now we have the following proposition (see [P08, Lemma 3.5]).

**Proposition 3.7.** The hypertoric manifold \( (M, T) \) is independent, up to \( T^n \)-equivariant isometry, of the coorientation of the hyperplane arrangement \( \mathcal{H} \) of \( M \).

By using Proposition 3.5 and 3.7, we have Theorem 1.1.
4. Nishimura’s suggestion and the future prospects

Several days later after the author’s talk in RIMS, Nishimura suggested that the set of hypertoric manifolds up to $T^n$-equivariant diffeomorphism is the very special case in the set of hypertoric varieties. We will introduce about that in this final section, and give the problem for the case of all (hyper)toric varieties.

Let $+k_i$ (resp. $-k_i$) be the number of hyperplanes whose coorientation vector is $e_i$ (resp. $-e_i$) in $\mathbb{R}^n$, where $e_i$ (resp. $-e_i$) is the canonical basis such that the $i$-th coordinate 1 (resp. $-1$) and the other coordinates are 0 in $\mathbb{R}^n$. Let $k_0$ be the number of hyperplanes whose coorientation vector is $\sum_{i=1}^n v_i$, where $v_i = e_i$ or $-e_i$. Now we may define two types of hypertoric manifolds by using these hyperplanes as follows:

(1) $M_0(k_1, \ldots, k_n)$;
(2) $M_1(k_0, \pm k_1, \ldots, \pm k_n)$,

where the hyperplane of $M_1$ which corresponds to $k_0$ is determined by the sign of $\pm k_i$ for all $i = 1, \ldots, n$. Because of Proposition 2.1 and 2.2, we can denote all hypertoric manifolds up to $T^n$-equivariant diffeomorphism as one of the above manifolds (up to simultaneous sign changing). Therefore, the fact that the $T^n$-equivariant diffeomorphism types of hypertoric manifolds are determined by the $H^*(BT; \mathbb{Z})$-algebraic types of $H_T^*(M; \mathbb{Z})$ (see Corollary 1.2) is almost trivial. However, as we seen in Section 3, two hyperplane arrangements determined by $H_T^0(M; \mathbb{Z})$ and $H_T^*(M'; \mathbb{Z})$ (they are algebraic isomorphic) are same not only their combinatorial types but also their position of hyperplanes. It follows that the $H^*(BT; \mathbb{Z})$-algebraic structure of $H_T^*(M; \mathbb{Z})$ can determine not only the $T$-equivariant diffeomorphism of $(M, T)$ but also $T$-equivariant isometry of $(M, T)$ (see Theorem 1.1).

According to the above comments by Nishimura, we know that the really important objects in hypertoric varieties are orbifolds. Fortunately, if we take the coefficient as the rational number $\mathbb{Q}$ then Theorem 2.5 is true for the hypertoric orbifolds. However, we can easy to construct two distinct hyperplanes (angles of intersections of hyperplanes are different) from two $H_T^0(M; \mathbb{Q})$ and $H_T^*(M'; \mathbb{Q})$ (they are same up to $H^*(BT; \mathbb{Q})$-algebra). It follows that the orbifold analogue of Corollary 1.2 for $\mathbb{Q}$-coefficient does not hold. Moreover, to compute $H_T^*(M; \mathbb{Z})$ is very complicated for hypertoric orbifolds as well as toric orbifolds. Because of the singularity of orbifolds, there is the torsion element appears in $H_T^*(M; \mathbb{Z})$.

In order to consider the space with singularities, we can use the intersection cohomology $IH^*(M)$ or the equivariant intersection cohomology $IH_T^*(M)$. The intersection cohomology is considered as the “true” cohomology theory for the spaces with singularities. Actually, the equivariantly formality satisfies for $IH_T^*$ but it does not satisfy for $H_T^*$ if the space has singularities (see [GKM98], [BP09]). In this year (2009), Braden-Proudfoot determines the equivariant intersection cohomology of hypertoric varieties $IH_T^*(M)$ by using the functorial method in [BP09]. So, finally, we may ask the following problem as the orbifold analogue of Theorem 1.2 by using the equivariant intersection cohomology.

PROBLEM 4.1. Does equivariant intersection cohomology determine (hyper)toric orbifold? In other words, if $IH_T^*(M) \cong IH_T^*(M')$ satisfies for two (hyper)toric orbifolds then is there a $T$-equivariant map $f : M \to M'$ such that $f$ is a homeomorphism which preserves the singularities?

If we have the affirmative answer in this problem, it corresponds to the generalizations of the main results in [M08] and [Ku2] to the orbifold case.

Acknowledgements

Finally the author would like to thank Professor Yasuzo Nishimura for his invaluable advices and comments. He also would like to thank Professor DongYoup Suh for providing excellent circumstances to do research.
