Role of SLX4 in ICL repair

Interstrand cross-links (ICLs) block replication and transcription and are thus extremely cytotoxic. In higher eukaryotes, ICLs processing involves the Fanconi anemia (FA) pathway and homologous recombination (HR). Stalled replication forks activate the eight-subunit FA core complex, which ubiquitylates FANCD2-FANCI. Once post-translationally modified, this heterodimer recruits downstream members of the ICL repairosome, including the FAN1 nuclease. However, ICL processing has been shown to involve also MUS81-EME1 and XPF-ERCC1, nucleases known to interact with SLX4, a docking protein that can bind also another nuclease, SLX1. To investigate the role of SLX4 more closely, we disrupted the SLX4 gene in avian DT40 cells. SLX4 deficiency caused cell death associated with extensive chromosomal aberrations including a significant fraction of isochromatid-type breaks, where sister chromatids were broken at the same site. SLX4 thus appears to play an essential role in cell proliferation, probably by promoting the resolution of inter-chromatid HR intermediates. Because ubiquitylation plays a key role in the FA pathway, and because the N-terminal region of SLX4 contains a ubiquitin-binding zinc finger (UBZ) domain, we asked whether this domain is required for ICL processing. We show that SLX4<sup>−/−</sup> cells expressing UBZ-deficient SLX4 were sensitive selectively to ICL-inducing agents, and that the UBZ domain was required for interaction of SLX4 with ubiquitylated FANCD2 and for its recruitment to DNA-damage foci generated by ICL-inducing agents. Our findings thus suggest that ubiquitylated FANCD2 recruits SLX4 to DNA damage sites, where it mediates the resolution of recombination intermediates generated during the processing of ICLs.
Role of SLX4 in ICL repair

INTRODUCTION

Interstrand cross-links (ICLs) inhibit transcription and replication. Their considerable cytotoxicity has been ascribed primarily to their blocking of replication forks, and it is this phenomenon that is believed to be responsible for the success of ICL-inducing agents such as cisplatin and mitomycin-C (MMC) in cancer chemotherapy (1). ICL processing is complex, inasmuch as it involves proteins from several distinct pathways of DNA metabolism. In higher organisms, it is orchestrated by the Fanconi anemia (FA) pathway (2, 3). Collision of replication forks with ICLs activates the ATR kinase, which in turn licenses the FANCL ubiquitin ligase subunit of the FA core complex (composed of FANCA, B, C, E, F, G, L and M proteins) to modify the FANCD2-FANCI heterodimer (2, 4-6). The mono-ubiquitylated FANCD2-FANCI complex is then targeted to chromatin (7, 8), where it recruits downstream components of the repairosome including the structure-specific nuclease FAN1 (9-12). However, ICL processing requires also other enzymes, such as the nucleases MUS81-EME1 and XPF-ERCC1 and it is currently not known how these are recruited to sites of damage in ICL repair.

The structure-specific endonucleases XPF-ERCC1 and MUS81-EME1, which are implicated in ICL repair and in the resolution of homologous recombination (HR) intermediates (13-22), interact with SLX4. The latter polypeptide interacts also with SLX1 both in yeast (23, 24) and in mammalian cells (21, 22, 25, 26) and the resulting complex displays 5’-flap endonuclease and Holliday junction resolvase activities. Based on this evidence, SLX4 has been assigned the role of a docking platform for structure-specific endonucleases and its pivotal role in regulating their activities is underscored by the finding that SLX4 downregulation sensitisizes human cells to a wide variety of DNA-damaging agents (21, 22, 25, 26). However, although SLX4 has been implicated also in ICL repair, its role in this process, as well as its possible link to the FA pathway remains to be elucidated.

In this study, we set out to characterize the biological role of SLX4 by conditionally disrupting the SLX4 gene in chicken DT40 cells (27). We now report that loss of SLX4 induces cell death associated with extensive chromosome aberrations, which shows that SLX4 plays a key role in the repair of spontaneous DNA damage. Many proteins interacting with ubiquitylated polypeptides contain so-called
Role of SLX4 in ICL repair

ubiquitin-binding zinc finger (UBZ) domains (28). Because ubiquitylation plays an important role in ICL repair, we asked whether the UBZ domain of SLX4 is required for DNA damage processing. We show here that this domain is essential for the recruitment of SLX4 to sites of DNA damage upon exposure of cells to cross-linking agents, and that this recruitment is dependent on FANCD2 ubiquitylation. Consistently, the UBZ domain of SLX4 is required for interaction with mono-ubiquitylated FANCD2. Our data thus indicate that SLX4 involvement in ICL repair is controlled by the FA pathway.

RESULTS

SLX4 is essential for cell proliferation. To disrupt the SLX4 gene, we used gene-targeting constructs designed to delete the five exons that encode residues 124 to 518 of the protein (Fig. S1A). However, we failed to generate SLX4−/− cells, which suggested that SLX4 is essential for DT40 cell survival. We therefore first disrupted one SLX4 allele and stably transfected the SLX4+/− cells with constructs expressing the tTA repressor, and the chicken SLX4 transgene under the control of doxycycline-repressible promoter (tetSLX4) (29). We then disrupted the second SLX4 allele and confirmed the successful disruption by Southern blotting (Fig. S1B). RT-PCR analysis showed that the SLX4−/−tetSLX4 cells expressed SLX4 mRNA, and that this transcript was undetectable in doxycycline-treated cells after 72 h (Fig. 1A). The SLX4+/−tet SLX4 cells proliferated slightly slower than wild type (WT) cells, possibly due to nonphysiological levels of expression of SLX4 (Fig. 1B). 24 h after the addition of doxycycline, the SLX4 transcript was barely-detectable (Fig. 1A), and the proliferation of the SLX4+/−tetSLX4 cells slowed down considerably (Fig. 1B). After 48 h doxycycline treatment, the SLX4+/−tetSLX4 cells accumulated in the G2 phase of the cell cycle, with many cells dying (Fig. 1C), indicating that SLX4 is essential for cell proliferation at least in DT40 cells. This result is marked contrast with the viability of SLX4 knockout mice (30). This difference might possibly be attributable to the absence of the MUS81 gene in the chicken genome. Chromosome analysis of mitotic cells showed an increased number of spontaneous chromosomal aberrations, as seen in HR-deficient cells (Table S1). The above-described phenotypic traits were observed in two independent SLX4+/−tetSLX4 clones, which argues against clone-specific effects and demonstrates that SLX4 plays a pivotal role in the repair of spontaneous DNA damage (Fig. 1D, Table S1).
Role of SLX4 in ICL repair

**SLX4 is required for HR-dependent DSB repair.** To assess the role of SLX4 in HR-dependent double strand break (DSB) repair, we exposed the $SLX4^{-/-}tetSLX4$ cells to $\gamma$-rays (2 Gy) 48 h after the addition of doxycycline, harvested mitotic cells 3 h later and counted the number of chromosomal breaks. Using this protocol, we were able to selectively evaluate HR-dependent DSB repair in the G2 phase, because only cells irradiated in G2, and not in S, enter mitosis within 3 h, and also because cells in the G2 phase preferentially use HR for DSB repair (31, 32). In WT cells, ionizing radiation induced predominantly chromatid-type breaks (breaks in one sister chromatid). In SLX4-depleted cells, a marked increase in the total number of chromosomal breaks was observed, coupled to a shift from chromatid-type to isochromatid-type breaks (breaks at the same site of both sister chromatids) (Fig. 1D, Table S1). The latter type of break is probably caused by HR-dependent repair between the broken and the intact sister chromatids, followed by defective resolution of recombination intermediates (33). Taking a role of SLX1(21, 26), XPF-ERCC1 (34-36), and MUS81-EME1 (37, 38) in HR into account, our findings thus support the hypothesis that SLX4 deficiency causes impaired resolution of HR intermediates, possibly through the disruption of functional SLX4 complex including these structure-specific endonucleases.

The UBZ domain of SLX4 plays a key role in ICL repair. To elucidate the role of the UBZ domain of SLX4, we generated mutant SLX4 cDNA lacking the UBZ domain, and stably transfected $SLX4^{+/+}tetSLX4$ cells with vectors carrying either the mutant ($SLX4-UBZ\Delta$) or WT cDNA ($SLX4-wt$). We then treated the $SLX4-wt$ and $SLX4-UBZ\Delta$ cells with doxycycline for 5 d to repress the tetSLX4 transgene. We confirmed that the protein levels of $SLX4-wt$ and $SLX4-UBZ\Delta$ were similar (Fig. S2), which showed that deletion of the UBZ domain did not affect SLX4 stability. As expected, the $SLX4-wt$ cells displayed essentially the same phenotype as doxycycline-untreated $SLX4^{+/+}tetSLX4$ cells, including cellular sensitivity to DNA damage (Fig. S3). Interestingly, constitutive expression of $SLX4-UBZ\Delta$ in doxycycline-treated $SLX4^{+/+}tetSLX4$ cells allowed the cells to proliferate similarly to doxycycline-untreated $SLX4-UBZ\Delta$ and the parental $SLX4^{+/+}tetSLX4$ cells, indicating that the UBZ domain is dispensable for cellular proliferation (Fig. S4). We next asked whether cells expressing SLX4-UBZ\Delta were sensitized to DNA damage. As shown in Fig. 2, the $SLX4-UBZ\Delta$ cells were sensitive to...
Role of SLX4 in ICL repair

all ICL-inducing agents tested (cisplatin, melphalan, and MMC), but not to the other genotoxic agents (methylmethane sulfonate, UV light, ionizing radiation, topoisomerase I poison [camptothecin] and topoisomerase II inhibitors [VP-16 and ICR193]) (Fig. 2 and Fig. S5). Given that sensitivity to ICL-inducing agents is a common phenotypic trait of FA cells (2, 39), we hypothesized that the UBZ domain might link SLX4 to the FA pathway.

Recruitment of SLX4 to DNA damage sites requires the SLX4 UBZ domain and mono-ubiquitylated FANCD2. Disruption of the FA core complex abolishes DNA damage-induced ubiquitylation of FANCD2, as exemplified for FANCC cells (Fig. S6). As MMC treatment did not affect FANCD2 modification in SLX4-UBZΔ or SLX4-/-tetSLX4 cells treated with doxycycline for 48 h (Fig. S6), we concluded that SLX4 is not required for the activation of the ubiquitin ligase activity of the FA core complex.

Following treatment with DNA damaging agents, FANCD2 and other repair proteins accumulate in subnuclear foci (7-9). In order to find out whether SLX4 also accumulated in these foci, we stably transfected DT40 cells with a vector expressing an SLX4-GFP fusion protein. After treatment of the transfected cells with MMC for 6 h, SLX4-GFP foci became detectable and co-localized with those containing FANCD2 (Fig. 3A). That MMC-induced SLX4-GFP foci failed to form in similarly transfected FANCC- and FANCD2-K563R (40) DT40 lines, in which mono-ubiquitylation of FANCD2 is impaired (40, 41), indicated that FANCD2 mono-ubiquitylation is required for SLX4 recruitment to damage sites (Fig. 3A).

We next asked whether the above recruitment required the UBZ domain of SLX4. As shown in Fig. 3A, the SLX4-UBZΔ-GFP mutant protein failed to form MMC-induced foci in WT DT40 cells, even though FANCD2 foci formed normally (Fig. 3A). The recruitment of SLX4 to MMC-induced DNA damage sites is thus dependent on both the SLX4 UBZ domain of and mono-ubiquitylated FANCD2.

The above co-localization suggested that SLX4 and FANCD2 interacted. In order to document this interaction, we immunoprecipitated the SLX4-GFP or SLX4-UBZΔ-GFP proteins from extracts of stably-transfected DT40 WT cells with an anti-GFP antibody and probed the precipitates for the presence of FANCD2. As shown in Fig. 3B, mono-ubiquitylated FANCD2 was present in immunoprecipitates isolated
Role of SLX4 in ICL repair

from extracts of MMC-treated cells expressing SLX4-GFP, but not SLX4-UBZΔ-GFP. These data indicate that SLX4 forms a complex with mono-ubiquitylated FANCD2 and that this interaction requires the SLX4 UBZ domain. It remains investigated whether or not this interaction is direct.

The FA pathway and SLX4 are not fully epistatic in ICL processing. Having established that SLX4 interacts with mono-ubiquitylated FANCD2, we set out to test whether the involvement of SLX4 in ICL processing is fully dependent on this interaction. To this end, we deleted the FANCC gene in SLX4-UBZΔ as well as in SLX4ΔtetSLX4 cells. We then treated two independently isolated FANCC/SLX4-UBZΔ clones with doxycycline for 5 d and analyzed their phenotype. We also analyzed a FANCC/SLX4ΔtetSLX4 clone that was not treated with doxycycline. Surprisingly, the FANCC/SLX4-UBZΔ cells displayed higher sensitivity to MMC and cisplatin than either single mutant (Fig. 4A, and Fig. S7). Thus, in spite of its association with FANCD2, SLX4 appears to participate in the processing of ICLs also independently of the FA pathway.

We next analyzed chromosomal aberrations in MMC-treated mitotic cells. SLX4-UBZΔ as well as FANCC/SLX4ΔtetSLX4 cells showed increased numbers of chromosomal aberrations compared to WT DT40 cells. That FANCC/SLX4-UBZΔ cells displayed a larger number of chromosomal aberrations than either SLX4-UBZΔ or FANCC/SLX4ΔtetSLX4 cells (Fig. 4B, Table S2) faithfully reflects the greater sensitivity of the former cells to MMC (Fig. 4A and Fig. S7). Thus, SLX4 and the FA pathway appear to contribute to ICL repair also independently of each other.

DISCUSSION
In this study, we demonstrate that SLX4 is required for HR-dependent DSB repair, possibly for resolution of recombination intermediates, at least as implied by the substrate specificity of its complex with SLX1 (21, 26). We also show that SLX4 is recruited to sites of DNA damage by mono-ubiquitylated FANCD2 and that this recruitment requires the SLX4 UBZ domain. Thus, ubiquitylation of FANCD2 by the FA core complex has at least two functions: the recently-described recruitment of FAN1 (9-12) and the recruitment of SLX4 documented in the present study.

The following lines of evidence support the conclusion that SLX4 participates
Role of SLX4 in ICL repair

in ICL repair downstream of mono-ubiquitylated FANCD2. (i) Deletion of SLX4 UBZ domain sensitized cells selectively to ICL-inducing agents, but not to other DNA damaging agents tested (Fig. 2). (ii) SLX4 recruitment to DNA-damage sites was dependent on FANCD2 mono-ubiquitylation (Fig. 3). (iii) This recruitment required the ubiquitin-binding domain of SLX4 (Fig. 3). (iv) SLX4 interaction with ubiquitylated FANCD2 required the SLX4 UBZ domain (Fig. 3). (v) Recent reports show FA patients carrying mutations in the \textit{SLX4} gene including deletion of the UBZ domain (42, 43).

However, \textit{FANCC}/\textit{SLX4}-UBZ\textDelta{} cells displayed a more severe phenotype than \textit{SLX4}-UBZ\textDelta{} cells, which indicated that the FA pathway regulates repair enzymes other than those associated with SLX4. The most likely candidate is the recently-identified FAN1 nuclease (9-12). Similarly to cells lacking both FANCC and SLX4, \textit{FANCC}/\textit{FAN1}1/\textDelta{} DT40 cells were also more sensitive to ICL-inducing agents than cells lacking solely FAN1 (44). Thus, the FA pathway appears to control, and possibly co-ordinate, the action of the nucleases SLX1, XPF-ERCC1 and MUS81-EME1 that are known to associate with SLX4, as well as FAN1. Moreover, the \textit{FANCC}/\textit{SLX4}-UBZ\textDelta{} cells displayed a more severe phenotype than \textit{FANCC} cells, which indicated that the UBZ domain of SLX4 might interact also with targets other than FANCD2, possibly proteins ubiquitylated by UBC13 (45).

Interestingly, ICL-induced chromosomal exchanges, a hallmark of FA cells (39) observed in \textit{FANCC}/\textit{SLX4}-tetSLX4 cells was significantly suppressed by deletion UBZ domain of SLX4 (2/50 in \textit{FANCC}/\textit{SLX4}-UBZ\textDelta{} cells vs 6/50 in \textit{FANCC}/\textit{SLX4}-tetSLX4 cells, Fisher's exact test \(p=0.0374\), Fig. 4, Table S2). Moreover, loss of FAN1 also suppresses chromosomal exchanges in FA cells following treatment with ICL-inducing agents (44). These data suggest that exchanges in FA deficient cells are attributable to the inappropriate resolution of HR intermediates by FAN1 and SLX4 associating nucleases. Taken together, the FA pathway appears to direct SLX4 to a subset of HR intermediates, where it prevents a specific type of chromosomal aberrations. In the absence of FA-mediated recruitment, the UBZ domain of SLX4 may interact with other ubiquitylated protein(s), resolve these HR intermediates differently and thus give rise to different types of chromosomal aberrations. The loss of the SLX4 UBZ domain would abolish also the FA-independent interactions and the pattern of chromosomal aberrations would alter yet again (Fig. S8).

The role of SLX4 in DNA repair is believed to be that of a docking platform

Yamamoto et al. 8
Role of SLX4 in ICL repair

for SLX1, MUS81-EME1 and XPF-ERCC1 structure-specific nucleases, as well as other proteins (21, 26). The viability of null mutants in genes encoding these nucleases (19, 46, 47) contrasts with the lethality of SLX4 disruption. It suggests that the nucleases are largely redundant in the processing of spontaneous DNA damage and the SLX4 deletion results in a loss of function of more than one of these enzymes. Should this be the case, then cells in which two or more endonuclease genes were disrupted would be anticipated to display a more severe phenotype than the single mutants. This is indeed the case, as our preliminary finding shows that disruption of the XPF gene in MUS81-deficient DT40 cells is lethal (manuscript in preparation). Given that these endonucleases share a preference for 3’-flap substrates, their inactivation might result in a total loss of this activity from the repairosome responsible for the resolution of HR intermediates and thus in lethality. Similarly, it might be anticipated that cells lacking FAN1 and SLX1 would also be non-viable due to the loss of 5’-flap endonuclease activity of the complex responsible for resolution of HR intermediates.

Our present work extends the studies with the yeast and human SLX4 homologues (21, 22, 24, 26) and confirms that SLX4 fulfills a key role as an interacting platform for enzymes involved in the processing of HR intermediates and links SLX4 also to the repair of ICLs, a process co-ordinated by the FA pathway.

METHODS
Additional details are provided in SI Materials and Methods.

Chicken SLX4 cloning and gene-targeting vectors. Full-length chicken Slx4 cDNA was amplified with PCR using the primers 5’-CCAATGGATGAACAGGACAATGA-3’ and 5’-GAAACGATACTGAATGGATCCC-3’ and cloned using a TOPO cloning kit (Invitrogen). SLX4 targeting vector was constructed to replace 5 exons (5th-9th) with a resistance (Puro and HisD) gene cassette flanked by loxP signals at both ends. The primers used to amplify the left arm were 5’-AGGGACAAGTTGTGGTGAGG-3’ and 5’-GAAACGATACTGAATGGATCCC-3’, and the primers for the right arm were 5’-GCAAGGCGTAATTTGTTGGT-3’ and 5’-CCAAGCCAAAATTCTTTTCA-3’.

Generation of SLX4 conditional mutant cells. To generate SLX4−/− cells, SLX4-targeting vectors (Puro and HisD) linearized with EcoRV were transfected sequentially by electroporation (Bio-Rad). The genomic DNA of the transfectants was digested with BamHI, and the targeted clones were confirmed by Southern blot analysis.
Role of SLX4 in ICL repair

The probe used was 613 bp in length, a PCR-amplified fragment derived from chicken DT40 genomic DNA using the primer set 5’-CTCTGCTTTAATTCCAAGC-3’ and 5’-AATCAGTACTAAATGTGAGC-3’. The probe was labeled using the Alkphos Direct Labelling Module (GE Healthcare, Little Chalfont, UK). To generate SLX4+/− and SLX4−/− cells, wild-type DT40 cells were transfected sequentially with the SLX4 targeting vectors with PuroR and then HisDR. Although we identified 8 SLX4+/− clones from 39 PuroR clones analyzed, we obtained no SLX4+/− clones out of 268 HisDR clones tested. To obtain SLX4+/−tetSLX4 cells, one of the SLX4+/− clones was transfected with both the tetracycline-controlled trans-activator (tTA) gene (Invitrogen) and the conditional SLX4 expression construct. To generate SLX4+/−tetSLX4 cells, SLX4+/−tetSLX4 cells were transfected with the SLX4 targeting vector (HisDR). Expression of chicken SLX4 in the SLX4+/−tetSLX4 cells was measured by Reverse Transcription Polymerase Chain Reaction (RT-PCR) using the SuperScript™ III First-Strand system (Invitrogen, CA, USA) and the 5’-TGCAGGTGTCCACGCTTGGT-3’ and 5’-CCTATTCCAAGCTGGTGCTGG-3’ primers.

**Generation of SLX4-wt and SLX4-UBZΔ cells.** We removed the PuroR and BsrR cassettes from the SLX4+/−tetSLX4 cells by transiently expressing the Cre-recombinase. The resultant SLX4+/−tetSLX4 cells were transfected with a transgene, GgSLX4-wt or GgSLX4-UBZΔ. To construct the GgSLX4-UBZΔ gene, cloned GgSLX4 cDNA was amplified using the primers 5’-GAAAGCCTGGAGGATGCAGGC-3’ and 5’-GTTCCTCCTAAGATGCTTCT-3’, which resulted in the deletion of two UBZ motifs at the N-terminal region of SLX4. The expression vector was constructed by ligating together a β-actin promoter, GgSLX4-wt or GgSLX4-UBZΔ, and the drug-resistance marker gene (BsrR), in that order. We independently analyzed three clones, each of which grew with the same kinetics as the parent SLX4+/−tetSLX4 cells.

**Immunoprecipitation of SLX4-GFP.** DT40 cells carrying the SLX4-GFP or SLX4-UBZΔ-GFP transgene were treated with 1% formaldehyde for 5 min at room temperature and 62.5 mM glycine was added to stop the reaction. The cells were harvested and the cell extracts were prepared by sonicating the cell pellet in SDS lysis buffer (50 mM Tris-HCl, pH 8.0, 10 mM EDTA, 1% SDS) supplemented with a protease inhibitor cocktail (Roche). The cell extracts were diluted with dilution buffer (50 mM Tris-HCl, pH 8.0, 167 mM NaCl, 1.1% Triton X-100, 0.1% sodium deoxycholate) 20 fold. Whole cell extracts and immunoprecipitates were incubated with SDS elution
Role of SLX4 in ICL repair

buffer (10mM Tris-HCl, pH 8.0, 300mM NaCl, 5mM EDTA, 0.5% SDS) at 65°C for 4 h.

Supplemental Figure S8

DNA replication stalled at ICL

Wild-type

Proper regulation of ICL repair prevents exchange event

FANCC^−

Unregulated processing of ICL Exchange event

SLX4-UBZΔ

Partial defect in ICL repair

FANCC^−/SLX4-UBZΔ

ICLs remain unrepaired Massive increase in the number of breaks
