Abstract:

Thermal discoloration of cellulose (Avicel PH-101 and Whatman No. 42 filter paper) was studied in N₂ at 160-280 °C with glycerol-treated and NaBH₄-reduced samples, to understand the role of the reducing end. Thermal discoloration of glycerol-treated Avicel PH-101, in which some of the reducing ends were converted into glycosides (non-reducing ends), was suppressed compared with the original cellulose, and the level of suppression was directly related to the extent of glycosylation of the reducing ends. The stabilization efficiency of glycerol-treated Whatman No. 42 filter paper suggested that the reducing ends newly formed by reduction of the degree of polymerization (DP) (to about 200) during heat treatment contributed to the discoloration. The important role of the reducing ends in thermal discoloration was supported by the stabilization of Avicel PH-101 by reduction with NaBH₄ (giving a reducing end content that was 2% of that of the original cellulose). Thermally induced discoloration was also inhibited by heating cellulose in suspension in the polyether tetraethyleneglycol dimethylether, which has been reported to inhibit the thermal degradation of reducing sugars.

Keywords:

Cellulose; Thermal discoloration; Reducing end; Stabilization; Thermal glycosylation

1 Introduction

Cellulose is a major component of plant cell walls, and has been utilized in the paper, textile and plastics/chemicals (as derivatives) industries [1]. Due to its renewable character, cellulose utilization is expected to expand in broad areas of technology. For example, use of cellulose as a reinforcing material for plastics attracts a great deal of attention because of its favorable mechanical properties such as high tensile strength [2-4].

Discoloration of cellulose is sometimes problematic in preparation of cellulose-polymer composites [5-8]. Thermal degradation of cellulose is known to occur even at temperatures lower than 200 °C. Evolution of water, CO and CO₂ [9,10] and reduction of the degree of polymerization (DP) [9,10] have been reported, together with discoloration (yellowing) [11,12] in this temperature range. Consequently, the synthetic polymers that can be used for composite preparation with cellulose are limited to those with low melting points such as polyethylene and polypropylene [13]. The processing temperature is also limited to below 230 °C [5].

We reported previously that the reducing ends of Avicel PH-101 microcrystalline cellulose were converted into glycosides by heat treatment with alcohols at temperatures >140 °C [14]. Interestingly, the resulting alcohol-treated cellulose samples resisted discoloration on reheating at 240 and 280 °C. These results suggest that the cellulose reducing end is a reactive site in discoloration of cellulose at these temperatures.

We also found that reducing sugars were stabilized in polyether against thermal degradation including browning and polysaccharides and char formation [15]. This unexpected result was explained by the action of the ether oxygens as proton acceptors. This prevents proton donation to the oxygen atoms of the sugar through intra- and intermolecular hydrogen bonding, which may inhibit acid-catalyzed glycosylation and dehydration reactions. Such a stabilization effect is also expected at the cellulose reducing ends when heat treatment of cellulose is conducted in polyether.

In the present study, thermal discoloration of cellulose was investigated systematically with glycerol-treated and NaBH₄-reduced cellulose samples, to understand the role of the reducing end in thermal discoloration. Thermal discoloration of cellulose in the polyether tetraethyleneglycol dimethylether (TEGDE) was also compared with that in neat conditions.

2 Experimental

2.1 Materials

Avicel PH-101 (Asahi Kasei Co., Ltd., Japan) and Whatman No.42 filter paper (Whatman PLC, UK) were used as cellulose samples. The filter paper was cut into small pieces (3×3 mm), which were oven-dried at 105 °C for 24 h before use. Glycerol was purchased from Nacalai Tesque Inc., Japan. TEGDE was purchased from Tokyo Chemical Industry Co., Ltd., Japan.

2.1.1 Glycerol-treated cellulose

Glycerol-treated cellulose was prepared according to the method reported in our previous paper [14]. Cellulose (100 mg) and glycerol (200 mg) were placed at the bottom of a Pyrex glass tube reactor (internal diameter 8.0 mm, wall thickness 1.0 mm, length 300 mm). After the air inside the reactor was replaced with N₂ using an aspirator

connected through a three-way tap, the reactor was inserted into a muffle furnace preheated to various temperatures in the range 120-280 °C, through a small hole at the top of the furnace. After heating for 30 min (for Avicel PH-101) or 60 min (Whatman No.42 filter paper), the reactor was removed from the furnace and immediately cooled with flowing air (30 s) and then in cold water (30 s). The treated cellulose samples were washed with water (5×2 mL) then freeze-dried.

2.1.2 NaBH₄-reduced cellulose

The reducing ends of Avicel PH-101 were reduced with NaBH₄ according to the reported method [14]. Sodium borohydride (50 mg) was added to a suspension of Avicel PH-101 (1 g) in 0.1 N sodium carbonate buffer (pH 10, 20 mL) and stirred at 80 °C for 5 h. The pH of the reaction mixture was adjusted to 4.0 by addition of aq. 1 N HCl to terminate the reaction. After further stirring at 80 °C for 30 min, the suspension was neutralized by adding one drop of saturated aq. NaHCO₃ solution. These procedures were performed twice to complete the reduction. The NaBH₄-reduced cellulose sample was washed with 20 mL of aq. 0.001 N HCl, then with water (5×20 mL). After repeating the washing procedure one to five times, the sample was freeze-dried. Based on data from reducing group analysis by the 2,2'-bicinchoninic acid (BCA) method [14], the reducing end content of the reduced cellulose was only 2% of that of the unmodified cellulose.

The Na and B content of reduced samples with different washing times was quantified as follows. The reduced sample (100 mg) was incinerated in air in a muffle furnace at 600 °C for 2 h. The resulting ash was solubilized in distilled water (10 mL) and analyzed by ICP-MS with an Agilent 7500cs ICP-MS instrument.

2.2 Heat treatment

Heat treatment of various glycerol-treated and NaBH₄-reduced cellulose samples (20 mg) was conducted with a similar procedure to that described in section 2.1.1 (except for use of glycerol) for preparation of glycerol-treated cellulose samples. After heat treatment (N₂/120-280°C/30 min for Avicel PH-101 or 60 min for Whatman filter paper), the reactor was cooled with flowing air (30 s) and then in cold water. The cellulose samples were then analyzed without purification. Avicel PH-101 (100 mg) suspended in TEGDE (200 mg) was also heated in N₂ at 160-280 °C. These cellulose samples were filtered and washed with water (1.0 mL) to remove TEGDE, then freeze-dried.

2.3 Colorimetric analysis

Color was measured with a ZE6000 color meter (Nippon Denshoku Industries Co., Ltd.). CIELAB parameters (L*, a*, and b*) were determined in reflectance mode (JIS Z-8722) using illuminant C and 2° observer angle. Total color difference (ΔE^*) was calculated from the equation:

$$\Delta E^*=[(\Delta L^*)^2+(\Delta a^*)^2+(\Delta b^*)^2]^{1/2} \quad (1)$$

2.4 Gel permeation chromatography (GPC)

Molecular weight (MW) distribution was evaluated by GPC for phenyl carbamate derivatives of the celluloses. Sample (5 mg) and phenyl isocyanate (0.2 mL) were added to pyridine (2 mL), and the mixture stirred at 80 °C. After 24 h, the reaction mixture

became a yellow transparent solution. Methanol (0.5 mL) was then added to terminate the reaction, and the solvent was removed by evaporation *in vacuo* to give a dark yellow syrup. The phenyl carbamate derivatives were dissolved in tetrahydrofuran (THF), and analyzed by GPC with a Shimadzu LC-10A instrument under the following chromatographic conditions: column, Shodex LF-804; column temperature, 40 °C; eluent, THF; flow rate, 1.0 mL/min; detector, UV_{254nm}.

3 Results and discussion

3.1 Glycerol-treated cellulose

Figure 1 shows photographs of various glycerol-treated cellulose samples (Avicel and Whatman filter paper) that were prepared under N₂ at 120-280 °C. The photographs in the (b) lines are the glycerol-treated samples after heat treatment in N₂ at 240 °C for 30 min (Avicel) or 60 min (Whatman filter paper). The longer heating time for Whatman filter paper was used due to the higher stability of the filter paper to thermal discoloration. Figure 2 summarizes the changes in the CIE color parameters (L*, a* and b*) of these samples after heat treatment. Decrease of L* indicates brightness reduction; increase of a* and b* arises from color changes to red and yellow, respectively.

Untreated Avicel PH-101 was severely discolored after heat treatment at 240 °C for 30 min: L* decreased from 96.3 to 64.4, and a* and b* increased to 10.0 (from -0.6) and 30.7 (from 2.3), respectively. These parameter changes are consistent with the change of appearance in the control experiment. The glycerol-treated samples were stabilized toward this thermal discoloration, and the stabilization efficiency increased along with the increase in the glycerol treatment temperature. Changes in the CIE parameters also decreased for the glycerol-treated samples (Fig. 2).

In our previous paper [14], glycerol treatment at high temperature was reported to convert the cellulose reducing ends into glycosides via thermal glycosylation reaction. The reactivity of Avicel PH-101 to thermal glycosylation was not homogeneous. About 20% of the reducing ends reacted with glycerol at 140 °C, while the remainder became reactive at higher temperatures (>200 °C). This may arise from the crystalline nature of cellulose. The change in the reducing end content of Avicel PH-101 shown in Fig. 3 is consistent with the tendency of this thermal glycosylation. Interestingly, the color difference (ΔE^*) plotted against the glycerol treatment temperature exhibited the same trend as that of the reducing end content. These results strongly suggest that the cellulose reducing end is an important reaction site for thermal discoloration.

Inhibition of thermal discoloration was observed for the glycerol-treated Whatman filter paper samples (Figs. 1 and 2). However, the relationship between the stabilization efficiency and the glycerol treatment temperature was different from that for Avicel PH-101. Although the CIE parameter changes after heat treatment were reduced with increase in the glycerol treatment temperature in the case of Avicel PH-101 (Fig. 2), the CIE parameter changes for Whatman filter paper were not simply related to temperature. The stabilization efficiency of Whatman filter paper became greater at temperatures >200 °C.

These differing results can be explained by considering the change in DP of Whatman filter paper during glycerol treatment and heat treatment. Figure 4 shows the results of GPC analysis of the glycerol-treated Whatman filter paper samples. The chromatogram obtained from heat treatment of untreated cellulose (control sample) at

240 °C for 60 min is also included. The degree of polymerization (DP) of cellulose is known to be reduced during heat treatment to about the leveling-off DP (~200) [16]. The DP of Avicel PH-101 had already attained the leveling-off DP, since the preparation process included a mild acid hydrolysis step. By contrast, DP reduction was observed for Whatman filter paper (control) during heat treatment. The resulting newly formed reducing ends may contribute to thermal discoloration.

Similar DP reduction was also observed in preparation of the glycerol-treated Whatman filter paper samples, and the reduction became significant with increase in the treatment temperature. It was found previously [14] that the newly formed ends in glycerol are not reducing ends but glycosides with glycerol, since solvolysis takes place in glycerol. Thus the higher stabilization efficiency of the glycerol-treated Whatman filter paper samples obtained at 200, 240 and 280 °C is explainable as follows. Reducing end formation resulting from the DP-reduction was not important in heat treatment of these cellulose samples, because their DPs were already reduced to around the leveling-off DP and their reducing ends were blocked as glycosides.

3.2 Influence of NaBH₄ reduction

Cellulose reducing ends can be converted into glucitol moieties by reduction with NaBH₄ [14]. To confirm the important role of the reducing ends, the thermal discoloration behavior of NaBH₄-reduced Avicel PH-101 was compared with that of the original cellulose. Treatment of Avicel PH-101 with NaBH₄ in aqueous 0.1 N sodium carbonate buffer (pH10) decreased the reducing end content to about 2% of that of the original cellulose. Figure 5 shows the boron (B) and sodium (Na) contents in NaBH₄-reduced Avicel PH-101 samples prepared with different washing times with aqueous 0.001 N HCl solution. The B and Na contents were reduced from 650 and 280 ppm (no acid washing) to around 20 and 5 ppm, respectively, after repeating the acid washing procedure more than twice. Since the B and Na contents in the original Avicel PH-101 were 2.7 ppm (B) and 0.7 ppm (Na), these elements are contaminants from NaBH₄. Boronate and its Na salt remaining in the reduced cellulose samples could not be removed completely by washing with water, but acid washing can decompose the boronates that are formed with cellulose hydroxyl groups.

Figure 6 shows photographs of the NaBH₄-reduced samples after heat treatment in N₂ at 240 °C for 30 min, together with their color difference (ΔE^*) parameters. Thermal discoloration was clearly inhibited for the NaBH₄-reduced Avicel PH-101 samples, and the extent of inhibition was dependent on the acid washing time, hence on the B and Na contents. Generally, inorganic substances enhance char formation [17-21]. Thus without acid washing, the residual inorganic substances arising from NaBH₄ treatment would enhance discoloration. The lower stabilization efficiency of this sample may arise from such an influence of the inorganic substances. Stabilization against thermal discoloration observed for the NaBH₄-reduced Avicel PH-101 supports the hypothesis that the reducing end is a reactive site for thermal discoloration.

3.3 Heat treatment in polyether

Matsuoka et al. [15] found that thermal degradation of reducing sugars is inhibited in polyether, and proposed an inhibition mechanism in which an aprotic polyether acts as a base through hydrogen bonding to the hydroxyl groups of a sugar. This prevents proton donation to the oxygen atoms of sugar, which results in inhibition of

acid-catalyzed reactions such as glycosylation and dehydration. These findings suggest that the reducing ends of cellulose can be stabilized in polyether.

Figure 7 shows the discoloration behavior of Avicel PH-101 in TEGDE; the corresponding changes in the CIE parameters are summarized in Fig. 8. Discoloration of Avicel PH-101 tended to be enhanced by heat treatment for 30 min at the higher temperatures (>200-240 °C), and at 280 °C the color became almost black. The temperature effect on this thermal discoloration was similar to that for thermal glycosylation in glycerol (Fig. 3). In accordance with the change in the appearance, L* decreased, and a* and b* increased except for b* at 280 °C. Thermal discoloration was effectively inhibited in TEGDE. The water-soluble portions including TEGDE obtained at 240 and 280 °C had a slightly yellow color, but the color intensity was not sufficient to explain the inhibition of discoloration by solubilization of the colored substances. Thus, polyether is effective for inhibition of the thermal discoloration of cellulose. These results also support the proposal that the reducing end plays an important role in thermal discoloration.

3.4 Role of reducing end in thermal discoloration of Avicel PH-101 and Whatman filter paper

As noted above, thermal discoloration was different for Avicel PH-101 and Whatman filter paper. The lower stability of Avicel PH-101 to thermal discoloration arose from the larger number of reducing ends in the cellulose molecules, many of which are formed during acid hydrolysis in the preparation process. Whatman filter paper with higher DP has fewer reducing ends, which may enhance stability to thermal discoloration to a greater extent than for Avicel PH-101. Thermal discoloration of Whatman filter paper became significant when DP-reduction to form additional reducing ends occurred during heat treatment.

Thermal glycosylation reactivity [14] indicated that most of the reducing ends in Avicel PH-101 become reactive at temperatures >200-240 °C, although about 20% of the reducing ends, probably in the non-crystalline region, are reactive even at 140 °C. The former temperature range is that in which thermal expansion of cellulose crystallites becomes significant; thermal discoloration of Avicel PH-101 also became significant in that temperature range. These results suggest the interesting possibility that the reducing ends formed in the crystalline regions of cellulose contribute more to thermal discoloration than those in the non-crystalline regions.

4 Conclusions

The glycerol-treated cellulose samples (Avicel PH-101 and Whatman No.42 filter paper) whose reducing ends were converted into glycosides were stabilized against thermal discoloration. These results suggest that the reducing end is an important reactive site for thermal discoloration. This hypothesis is supported by the stabilization of Avicel PH-101 by NaBH₄-reduction, and the inhibition of thermal discoloration of Avicel PH-101 in TEGDE, which is reported to inhibit the thermal degradation of reducing sugars.
