ABSTRACT

N-Acetylglucosaminyltransferase V (GnT-V) is one of the most relevant glycosyltransferases to tumor invasion and metastasis. Based on previous findings of molecular recognition between GnT-V and synthetic substrates, we designed and synthesized a p-iodophenyl-derivatized trisaccharide, 2-(4-iodophenyl)ethyl 6-O-[2-O-(2-acetamido-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranosyl]-β-D-glucopyranoside (IPGMG, 1) and its radiolabeled form, [125I]IPGMG ([125I]1), for use in assays of GnT-V activity in vitro. The tributyltin derivative, 2-[4-(n-tributylstannyl)phenyl]ethyl 6-O-[2-O-(3,4,6-tri-O-acetyl-2-acetamido-2-deoxy-β-D-glucopyranosyl)-3,4,6-tri-O-acetyl-α-D-mannopyranosyl]-2,3,4-tri-O-acetyl-β-D-glucopyranoside (21), was synthesized as a precursor for the preparation of [125I]1. The iododestannylation of 21 using hydrogen peroxide as an oxidant followed by deacetylation yielded [125I]1. When [125I]1 was incubated in GnT-V-expressing cells with a UDP-GlcNAc donor, the production of β1-6GlcNAc-bearing IPGMG (IPGGMG, 2) was confirmed by radio-HPLC. In kinetic analysis, 1 was found to be a good substrate with a $K_m$ of 23.7 µM and a $V_{max}$ of 159 pmol/h·µg protein. [125I]1 would therefore be a useful synthetic substrate for the quantitative determination of GnT-V activity.

1. Introduction

The sugar chains of glycoproteins on cell surfaces, which are constructed by glycosyltransferases and glycosidases, change during particular biological events including development, carcinogenesis, and malignant transformation. Numerous studies conducted in the last two decades have demonstrated that N-acetylglucosaminyltransferase V (GnT-V) is relevant to tumor invasion and metastasis. Since Cummings first reported its expression in mouse lymphoma cells in 1982,\(^1\) GnT-V has been shown to be highly expressed in various cancer cell lines and tissues from the early stages of tumorigenesis.\(^2\)–\(^8\) In addition, studies using GnT-V-deficient mice have directly demonstrated an essential role of GnT-V in tumor growth and metastasis.\(^9\),\(^10\)

GnT-V catalyzes the transfer of an N-acetylglucosamine (GlcNAc) residue from a donor, UDP-GlcNAc, to an acceptor, the mannose α1–6 side chain of the trimannosyl core of N-glycans, to form a GlcNAcβ1-6Man linkage. This activity has been assessed predominantly using radiolabeled donors or fluorescent-labeled acceptors. In the former case, the production of sugar chains, the non-reducing ends of which are modified with radiolabeled GlcNAc by the enzymatic reaction, is measured through the use of a UDP-[^3]H]GlcNAc or UDP-[^14]C]GlcNAc donor.\(^2\),\(^11\),\(^12\) However, there is a problem with specificity since UDP-GlcNAc functions as a substrate for many glycosyltransferases. In the latter case, a GnT-specific acceptor, GlcNAcβ1-2Manα1-3-(GlcNAcβ1-2Manα1-6)Manβ1-4GlcNAcβ1-4GlcNAc, is labeled with 2-aminopyridine to yield a fluorescent substrate (Gn,Gn-bi-PA). This acceptor is obtained from the carbohydrate moiety of human transferrin through laborious and time-consuming processes, repeated digestion with various enzymes, chemical modifications, and purification.\(^13\)–\(^15\) Moreover, the PA-oligosaccharide could still be a substrate of GnT-III.

Thus, we planned and produced a GnT-V-specific radiiodinated substrate for use in assays of GnT-V activity in vitro. First, to ensure a high degree of specificity, GlcNAcβ1-2Manα1-6Glc\(^12\),\(^16\)–\(^18\) was employed as the saccharide moiety on the basis of previous findings; (i) it could not be a substrate of GnT-I and GnT-IV because of the lack of an acceptor site for GnT-I and GnT-IV, i.e., a Man residue linked to the bisecting Man with an α1–3 linkage, (ii) it is a poor substrate of GnT-III because of the
replacement of the acceptor residue, i.e., bisecting Man, with Glc, and (iii) it already carries an GlcNAc residue that should be transferred by GnT-II. Second, the 1-hydroxyl of the reducing terminal Glc, which was adopted as a substitute of the bisecting Man, was conjugated with a hydrophobic phenethyl group without loss of activity.\textsuperscript{11,12,16–18} Finally, the radioiodine \textsuperscript{125}I was considered to be incorporated into the \textit{para}-position of the phenyl ring immediately before the biological assay because the \textit{para}-substitution of iodine is effective in preventing deiodination \textit{in vivo}.\textsuperscript{19} The \textit{p}-iodophenyl-derivatized trisaccharide, 2-(4-iodophenyl)ethyl 6-\textit{O}-[2-\textit{O}-(2-acetamido-2-deoxy-\textit{β}-\textit{D}-glucopyranosyl)-\textit{α}-\textit{D}-mannopyranosyl]-\textit{β}-\textit{D}-glucopyranoside, was expected to behave as a substrate for \textit{in vitro} assays of GnT-V activity.

Herein, we report synthesis of an unlabeled IPGMG (1), a \textsuperscript{125}I-labeled IPGMG ([\textsuperscript{125}I]1), and the N-acetylglucosaminylated product β1-6GlcNAc-bearing IPGMG (IPGGMG, 2). The reaction kinetics of [\textsuperscript{125}I]1 were evaluated in GnT-V-expressing cells and its recognition by GnT-V was compared with that of Gn,Gn-bi-PA. From these results, the usefulness of [\textsuperscript{125}I]1 for the GnT-V assay was assessed (Figure 1).

2. Results and Discussion

2.1. Chemistry.

For the synthesis of 1 and [\textsuperscript{125}I]1, glycosylation of 3,4,6-tri-\textit{O}-acetyl-2-\textit{O}-(3,4,6-tri-\textit{O}-acetyl-2-acetamido-2-deoxy-\textit{β}-\textit{D}-glucopyranosyl)-\textit{α}-\textit{D}-mannopyranosyl bromide (3) and 2-(4-iodophenyl)ethyl-2,3,4-tri-\textit{O}-acetyl-\textit{β}-\textit{D}-glucopyranoside (4) was used as a key reaction (Scheme 1).

Synthesis of the bromide 3 began with the condensation, which was promoted by silver trifluoromethanesulfonate and collidine, of benzyl 3-\textit{O}-benzyl-4,6-\textit{O}-benzylidene-\textit{α}-\textit{D}-mannopyranoside (5)\textsuperscript{20} and 3,4,6-tri-\textit{O}-acetyl-2-deoxy-2-phthalimido-\textit{β}-\textit{D}-glucopyranosyl bromide (6)\textsuperscript{21} to afford disaccharide 7 (57%). Subsequent treatment of 7 with hydrazine hydrate followed by acetylation yielded 8 (80%, two steps). Debenzylideneation of 8 in 70% AcOH and subsequent acetylation yielded intermediate 9 (80%, two steps), whose hydrogenolysis and acetylation afforded
octaacetate 10 (86%, two steps). Subsequent treatment of 10 with 30% HBr-AcOH afforded 3, which was used as the glycosyl donor for the next reaction (Scheme 2).

Synthesis of glycosyl acceptor 4 was achieved by the coupling of 2-(4-bromophenyl)ethyl alcohol and 2,3,4-tri-O-acetyl-6-O-allyloxy carbonyl-α-D-glucopyranosyl trichloroacetimidate (13) prepared from 1,2,3,4-tetra-O-acetyl-β-D-glucopyranose (11) in three steps: protection of the 6-OH group with an allyloxy carbonyl group that afforded 12, anomeric deacetylation of 12 with piperidine, and reaction with CCl₃CN in the presence of DBU that afforded the imidate 13. (Scheme 3).

Glycosylation of 2-(4-bromophenyl)ethyl alcohol with imidate 13 led to 2-(4-bromophenyl)ethyl 2,3,4-tri-O-acetyl-6-O-allyloxy carbonyl-β-D-glucopyranoside (14) (72%), which was subjected to palladium-catalyzed deallylation to afford 15 (94%). 15 was reacted with ethyl vinyl ether in the presence of a catalytic amount of pyridinium p-toluenesulfonate to form 16 (99%). At this point, replacement of the bromo group with an iodo group was investigated before developing the route to 1 and [¹²⁵I]1. The intermediate, 2-[4-(tributylstannyl)phenyl]ethyl 2,3,4-tri-O-acetyl-6-O-(1-ethoxyethyl)-β-D-glucopyranoside (17), was prepared from 16 using a bromo-to-tributyltin exchange reaction catalyzed by Pd(0) (47%). The tributyltin derivative 17 was readily converted to 2-(4-iodophenyl)ethyl 2,3,4-tri-O-acetyl-6-O-(1-ethoxyethyl)-β-D-glucopyranoside (18) by reaction with iodine (94%). Treatment of 17 and 18 with pyridinium p-toluenesulfonate in methanol yielded 19 (95%) and 4 (98%), respectively (Scheme 3).

The treatment of glycosyl donor 3 with glycosyl acceptor 4 in the presence of silver carbonate and silver perchlorate in dichloromethane and toluene yielded 20 (67%), which was deacetylated to furnish the target compound 1 (59%) (Scheme 4). Next, synthesis of the precursor of [¹²⁵I]1, 22, was attempted from which the tributyltin group was expected to be facilely replaced with a radioactive iodo group by iododestannylation to yield [¹²⁵I]1. However, deacetylation of 21, which was obtained by the condensation of 3 and 19 in the presence of silver perchlorate and collidine (43%), did not yield 22. Therefore, the tributyltin derivative 21 was transformed into the fully protected and radiolabeled trisaccharide [¹²⁵I]20 by an iododestannylation reaction using hydrogen peroxide as the oxidant.
Conventional deacetylation of [\textsuperscript{125}I]20 afforded the desired radioiodinated compound [\textsuperscript{125}I]1 (Scheme 4). It was anticipated that no-carrier-added preparation would result in a final product bearing a theoretical specific activity similar to that of \textsuperscript{125}I. The radiochemical identity of [\textsuperscript{125}I]1 was verified by co-injection with nonradioactive 1 and comparison of their HPLC profiles. The final radioiodinated compound [\textsuperscript{125}I]1 showed a single peak of radioactivity at the same retention time as that of nonradioactive 1. The radioiodinated product was obtained in 50% radiochemical yield with a radiochemical purity of > 95% after HPLC.

Finally, 2-(4-iodophenyl)ethyl 6-O-[2,6-di-O-(2-acetamido-2-deoxy-\textbeta-D-glucopyranosyl)-\textalpha-D-mannopyranosyl]-\textbeta-D-glucopyranoside (IPGGMG, 2), the N-acetylglucosaminylated product of 1, was synthesized starting with removal of the benzyliden group of 7 with 70% AcOH to afford 23 (83%). Selective silylation of 6-OH of the mannose unit with tert-butyldimethylsilyl chloride yielded 24 (94%), the remaining hydroxyl group of which was acetylated to afford 25 (99%). Treatment of 25 with pyridinium p-toluenesulfonate afforded 26 (75%), whose glycosylation with the bromide 6 promoted by silver trifluoromethanesulfonate and collidine yielded 27 (40%). Removal of the N-phthalimido groups with hydrazine hydrate and subsequent acetylation yielded 28 (93%, two steps). Cleavage of the benzyl groups of 28 by hydrogenolysis followed by acetylation yielded 29 (72%, two steps). Treatment of 29 in acetic anhydride with HBr yielded bromide 30. Glycosylation of 4 with bromide 30 promoted by silver carbonate and silver perchlorate yielded 31 (7%, two steps), which was sequentially deacetylated to furnish the target compound 2 (Scheme 5).

2.2. Biological Studies.

A typical HPLC profile of the GnT-V-reaction products of [\textsuperscript{125}I]1 is shown in Figure 2. The reaction products showed peaks at retention times of 21 and 30 min, respectively, identical to those of the nonradioactive compounds 2 and 1.

This result indicates that GnT-V catalyzes the transfer of a GlcNAc residue from UDP-GlcNAc to [\textsuperscript{125}I]1 to form a \textbeta1-6 linkage, providing evidence that [\textsuperscript{125}I]1 acts as a substrate for GnT-V.
The kinetics of the conversion of 1 to 2 by GnT-V were determined using the IPGMG solution containing $[^{125}\text{I}]1$. This radioiodinated substrate exhibited saturation kinetics at high substrate concentrations (Figure 3A). The data satisfied the Michaelis–Menten equation, originally developed for enzymatic kinetics. The kinetic parameters were $K_m = 23.7 \mu$M and $V_{\text{max}} = 159 \text{ pmol/h} \cdot \mu\text{g protein}$, determined from the double-reciprocal Lineweaver–Burk plot (Figure 3B). The $K_m$ value is one order of magnitude lower than that for a fluorescent substrate, Gn,Gn-bi-PA.

The novel radioiodinated substrate $[^{125}\text{I}]1$ was used to assay GnT-V activity in crude extracts of various tissues in normal rats. To compare the findings with previous results obtained using Gn,Gn-bi-PA as a substrate, we assayed the GnT-V activity under similar experimental conditions. The results are summarized in Table 1. This enzyme was uniformly distributed in rat tissues with relatively high activity levels in the small intestine and serum. A similar tendency was observed in a previous investigation using Gn,Gn-bi-PA. The reaction velocity using $[^{125}\text{I}]1$ was 3- to 22-fold greater than that using Gn,Gn-bi-PA. These findings demonstrate that 1 serves as a better substrate for GnT-V than Gn,Gn-bi-PA.

3. Conclusions

We successfully designed and synthesized a novel radioiodinated trisaccharide derivative, $[^{125}\text{I}]1$, as a synthetic substrate for GnT-V. $[^{125}\text{I}]1$ exhibited higher affinity than a fluorescent substrate, Gn,Gn-bi-PA, suggesting it to be the preferred acceptor for this enzyme. The present findings contribute to the development of sensitive in vitro GnT-V assays.

4.2. Iododestannylation Reaction.

The radiolabeled compound [$^{125}$I]20 was prepared from the corresponding tributyltin derivative 21 by iododestannylation. Briefly, to initiate the reaction, 10 μL of H$_2$O$_2$ (5%) was added to a mixture of a tributyltin derivative (100 μg/100 μL MeOH), 0.2 mCi sodium [$^{125}$I]iodide, and 20 μL of 0.1N HCl in a sealed vial. The reaction was allowed to proceed at room temperature for 30 min. The reaction mixture was neutralized with sodium bicarbonate, and extracted with ethyl acetate. The extract was evaporated
and methanol (100 µL) was added. To the solution was added sodium methoxide (28% in methanol, 1.6 µL). The reaction mixture was stirred at room temperature for 45 min, and neutralized with Amberlyst® 15. The residue was purified by HPLC on a Cosmosil 5C18 AR-300 column (4.6×150 mm) with an isocratic solvent of H₂O/acetonitrile (83/17) at a flow rate of 1.0 mL/min.

4.3. Enzymatic Reactions of Radioiodinated IPGMG.

GnT-V-transfected WiDr cells were used as the enzyme source. The protein concentration was measured by the Lowry method.²³ Lysate of GnT-V-overexpressing WiDr cells was incubated with MES buffer (125 mM, pH 6.25) containing 40 mM UDP-GlcNAc, 200 mM GlcNAc, 0.5% Triton X-100, and 10 mM EDTA for 10 min at 37°C. [¹²⁵I]IPGMG was then added, and the incubation continued for an additional 4 h. The reaction was stopped by heating at 100°C for 1 min. Enzymatic products were analyzed by HPLC on a TSK-GEL ODS-80TM column (4.6×150 mm) with an isocratic solvent of H₂O/acetonitrile (85/15) at a flow rate of 1.0 mL/min.

4.4. GnT-V Activities in Rat Tissues.

Animal experiments were conducted in accordance with our institutional guidelines, and the experimental procedures were approved by the Kyoto University Animal Care Committee. Various tissues from male Wistar rats weighing 240-260 g were homogenized in 4 volumes of 10 mM Tris-HCl buffer (pH 7.4) containing 0.25 M sucrose. After centrifugation at 900 × g for 10 min, the supernatants were collected and used as crude enzyme preparations. The GnT-V activity and protein concentration were determined according to the procedures described above.
