ABSTRACT

Background and aims Inflammatory bowel disease (IBD) is initiated and perpetuated by a dysregulated immune response to unknown environmental antigens such as luminal bacteria in genetically susceptible hosts. SR-PSOX/CXCL16, a scavenger receptor that binds phosphatidylserine and oxidised lipoprotein, has both phagocytic activity and chemotactic properties. The aim of this study was to investigate the role of SR-PSOX/CXCL16 in patients with IBD and experimental murine colitis.

Methods The serum levels of SR-PSOX/CXCL16 were measured in patients with IBD. The roles of SR-PSOX/CXCL16 in phagocytosis of bacterial components and cytokine production by macrophages from wild-type (WT) and SR-PSOX/CXCL16 knockout (KO) mice were assessed. Colitis was induced by administering dextran sulfate sodium (DSS) to WT and SR-PSOX/CXCL16 KO mice. Colonic inflammation was analysed by clinical, histological and immunological parameters. Finally, the effect of a monoclonal antibody (mAb) to SR-PSOX/CXCL16 on DSS-induced colitis and trinitrobenzene sulfonic acid-induced colitis models was evaluated.

Results Serum levels of SR-PSOX/CXCL16 correlated significantly with the disease activity of patients with IBD. Ex vivo experiments showed that SR-PSOX/CXCL16 was involved in both phagocytosis of bacterial antigens and the T helper 1 immune response through the production of interleukin 12 and interferon γ. In vivo murine experiments demonstrated the upregulated gene expression of SR-PSOX/CXCL16 in inflamed colonic tissues and the predominant expression of SR-PSOX/CXCL16 on macrophages. SR-PSOX/CXCL16 KO mice were less susceptible to colonic inflammation than were their WT littermates. Administration of SR-PSOX/CXCL16 mAb ameliorated the condition in the two different experimental colitis models.

Conclusions SR-PSOX/CXCL16 plays a critical role in colonic inflammation and could be a potential therapeutic target for patients with IBD.

INTRODUCTION

Inflammatory bowel diseases (IBDs), including Crohn’s disease (CD) and ulcerative colitis (UC), are chronic and relapsing-remitting conditions with unknown aetiology. Previous clinical and basic observations suggest that inflammation is initiated and perpetuated by a dysregulated immune response to unknown environmental antigens such as luminal bacteria in genetically susceptible hosts. Recent genome-wide association studies showed that genes involved in both innate and adaptive immune responses could be risk factors for developing IBD. Moreover, an abnormal response of intestinal macrophages to commensal bacteria was reported to result in chronic intestinal inflammation. Therefore, it is important to investigate the relationship between luminal bacteria and antigen-presenting cells (APCs) in the pathogenesis of IBD. Indeed, we showed that macrophage-targeting treatment ameliorates colonic inflammation in an experimental colitis model. Thus, the control of

Significance of this study

What is already known about this subject?

► Inflammatory bowel disease (IBD) is associated with a dysregulated immune response to unknown environmental antigens including luminal bacteria in genetically susceptible hosts.

► SR-PSOX/CXCL16 is associated with several inflammatory diseases.

► SR-PSOX/CXCL16 is constitutively expressed in the small intestine but not in normal colonic tissues.

► SR-PSOX/CXCL16 has two different biological activities: as a scavenger receptor and as a chemokine.

What are the new findings?

► Serum levels of SR-PSOX/CXCL16 correlated with the disease activity of IBD.

► SR-PSOX/CXCL16 expression is upregulated in inflamed colonic tissues and predominantly detected on macrophages.

► SR-PSOX/CXCL16 is involved in not only phagocytosis of bacterial antigens but also the T helper 1 immune response in the progression of colitis.

► SR-PSOX/CXCL16 monoclonal antibody ameliorated the condition in two different experimental colitis models.

How might it impact on clinical practice in the foreseeable future?

► Our data provide the first evidence for a critical role for SR-PSOX/CXCL16 in the progression of colonic inflammation ex vivo and in vivo. These data suggest that SR-PSOX/CXCL16 could be a potential therapeutic target for patients with IBD.
molecules related to macrophages appears to be a promising approach for the treatment of IBD.

Chemokines are a superfamily of small chemotactic cytokines and are classified into four major subfamilies on the basis of the motif of the first two cysteine residues: CC, CXC, C and CX3C subfamilies. The most important function of chemokines is the ability to regulate leukocyte trafficking and retention in lymphoid tissues and in peripheral tissues in both homeostasis and inflammation. The expression of several chemokines increases in the colonic tissues of both experimental murine colitis models and patients with IBD, and these chemokines are suggested to play a role in the pathophysiology of colitis.

SR-PSOX/CXCL16, a scavenger receptor that binds phosphatidylserine and oxidised lipoprotein, is a chemokine of the CXC family and has been identified as a novel transmembrane protein. In the static state, SR-PSOX/CXCL16 is expressed in various lymphoid tissues including the thymus, spleen, lymph nodes and Peyer’s patches, and in non-lymphoid tissues including the lung, liver, kidney and small intestine, but not colonic tissue. Among immune cells, SR-PSOX/CXCL16 is found primarily on the surface of APCs such as monocytes/macrophages and dendritic cells. SR-PSOX/CXCL16 has two different biological activities: as a scavenger receptor that mediates adhesion and phagocytosis of both Gram-positive and Gram-negative bacteria by APCs, and as a chemokine for CCR6-expressing cells such as naïve CD8 T cells, T helper 1 (Th1)-polarised CD4 and CD8 T cells, and natural killer T cells. The main functions of chemokines in IBD are suggested to play a role in the pathophysiology of colitis.

SR-PSOX/CXCL16 KO mice were generated in collaboration with Sankyo Co. (Tokyo, Japan) as described previously. Heterozygous mice were generated by crossing SR-PSOX/CXCL16 KO mice and C57BL/6 mice, and were intercrossed to obtain homozygous SR-PSOX/CXCL16 KO and wild-type (WT) littermates. The genotyping of F2 mice was performed by PCR at least twice using the following primers: 5′-TACCGAGG-TACATTTGGATCA-3′ and 5′-TTGCGCTCAAAGCAGTCCAC-TA-3′ for detection of the WT SR-PSOX/CXCL16 allele (551 bp), and 5′-GGATCTCCTGTGATCCTACCG-3′ and 5′-CCACACTGATGATCCAGAA-3′ for detection of the KO allele (533 bp). SR-PSOX/CXCL16 KO mice and their WT littermates from intercrosses of heterozygous mice were used in the experiments. C57BL/6 mice and SJL/J mice were purchased from Japan SLC (Shizuoka, Japan) and Charles River Japan (Kanagawa, Japan), respectively. All experiments were performed with female mice at 8–12 weeks of age according to the protocol approved by the Animal Protection Committee of our institution.

**Preparation of thioglycollate-elicited peritoneal macrophages**

SR-PSOX/CXCL16 KO and WT mice were injected intraperitoneally with 3 ml of 3% thioglycollate (Eiken Chemical Co., Tokyo, Japan) and peritoneal exudate cells (PECs) were harvested 4 days later. Cells were cultured with complete RPMI medium (RPMI 1640 medium (Gibco BRL, Eggenstein, Germany) supplemented with 10% heat-inactivated fetal bovine serum, 100 μg/ml streptomycin (Sigma Chemical Co., St Louis, Missouri, USA) and 100 μg/ml penicillin (Sigma Chemical Co.)) for 2 h and, after removal of non-adherent cells, adherent PECs were cultured as peritoneal macrophages. Adherent PECs were resuspended and adjusted to a concentration of 1×10^6 cells/ml.

**Preparation of caecal bacterial lysates (CBLs)**

CBLs were prepared directly from the caecal contents of SR-PSOX/CXCL16 KO and WT mice according to a protocol described by Cong et al. The sterility of the lysates was confirmed by culture.

**Human serum samples**

Human serum samples were obtained from 14 patients (11 men and 3 women; mean age, 27.8±6.4 years) with active CD, 16 patients (9 men and 7 women; 27.7±7.4 years) with inactive CD, 16 patients (10 men and 6 women; 27.2±15.6 years) with active UC, 13 patients (10 men and 3 women; 29.5±14.8 years) with inactive UC and 16 healthy volunteers (15 men and 1 woman; 34.6±5.1 years). The clinical characteristics of patients with CD and UC are shown in table 1. The disease activity of the patients with CD and UC was determined according to the Crohn’s Disease Activity Index (CDAI) and the Clinical Activity Index (CAI), respectively. A CDAI ≥150 and a CAI ≥5 was defined as active CD and active UC, respectively. Informed consent was obtained from all patients and volunteers, and the experimental design using these samples was approved by the Kyoto University Hospital Ethics Committee.

**Materials and methods**

**Human serum samples**

Human serum samples were obtained from 14 patients (11 men and 3 women; mean age, 27.8±6.4 years) with active CD, 16 patients (9 men and 7 women; 27.7±7.4 years) with inactive CD, 16 patients (10 men and 6 women; 27.2±15.6 years) with active UC, 13 patients (10 men and 3 women; 29.5±14.8 years) with inactive UC and 16 healthy volunteers (15 men and 1 woman; 34.6±5.1 years). The clinical characteristics of patients with CD and UC are shown in table 1. The disease activity of the patients with CD and UC was determined according to the Crohn’s Disease Activity Index (CDAI) and the Clinical Activity Index (CAI), respectively. A CDAI ≥150 and a CAI ≥5 was defined as active CD and active UC, respectively. Informed consent was obtained from all patients and volunteers, and the experimental design using these samples was approved by the Kyoto University Hospital Ethics Committee.
**Phagocytosis assay**
The ex vivo phagocytosis assay was performed using pHrodo
*Escherichia coli* BioParticles conjugate for phagocytosis (Invitrogen) according to the manufacturer’s instructions. The fluorescence intensity was measured using a microplate reader (Fluoroskan Ascent FL, Labsystems, Helsinki, Finland) at the indicated times. For fluorescence microscopic observation of phagocytosis, peritoneal macrophages were seeded at $3 \times 10^5$ cells/well in 8-well Lab-Tek chamber glass slides (NUNC Roskilde, Denmark) and incubated overnight in complete medium. The wells were washed with phosphate-buffered saline (PBS), fluorescent particles were added and the slides were observed using fluorescence microscopy (Olympus, Tokyo, Japan) at the indicated times.

**Stimulation and cytokine production assay of peritoneal macrophages**
Peritoneal macrophages were seeded at $2.5 \times 10^5$ cells/well in 48-well culture plates and incubated overnight in complete medium. Cells were primed with 500 U/ml interferon γ (IFNγ; R&D Systems, Minneapolis, Minnesota, USA) for 16 h and then stimulated with 100 ng/ml lipopolysaccharide (LPS (L5668-2ML); Sigma Chemical Co.) or 30 μg/ml CBL for 24 h. The supernatants were collected and subjected to analysis of cytokine production by ELISA.

**Induction of experimental colitis**
DSS-colitis was induced in SR-PSOX/CXCL16 KO mice, WT littermates and C57BL/6 mice using a modification of the method described by Inoue et al. Briefly, to induce colitis, $5\%$ DSS (molecular mass, 35–50 kDa; MP Biomedicals, Solon, Ohio, USA) in regular drinking water was administered for 5 days (from day 0 to 4), and then regular drinking water was given from day 5. Normal control mice received regular drinking water throughout the experiment. The mice were sacrificed on day 8 or day 14 to evaluate the acute inflammatory phase or the restitution phase, respectively. TNBS-colitis was induced in SJL/J mice using a modification of the method described by Neurath et al.

**The neutralising effect of mAb to SR-PSOX/CXCL16 on colitis models**
To investigate the effect of blocking SR-PSOX/CXCL16 on experimental colitis, C57BL/6 mice with DSS-induced colitis and SJL/J mice with TNBS-induced colitis were injected intraperitoneally with 500 μg of mAb to SR-PSOX/CXCL16 dissolved in 200 μl of PBS or an equal amount of control rat immunoglobulin G (IgG) (MP Biomedicals) in PBS once a day from days 1 to 7 and days 1 to 5, respectively.

**Microscopic assessment of colitis**
The colonic tissues were treated using the same method as in Matsuura et al. and then analysed histologically in a blind manner. Histological damage of DSS- and TNBS-induced colitis was quantified using the histological scoring system described by Williams et al. and Elson et al. respectively.

**Colon fragment culture**
Fragment culture of distal colon segments was performed according to the published method. Culture supernatants were collected and stored at $-80°C$ until assayed.

**Isolation and stimulation of mesenteric lymph node (MLN) cells**
MLNs were isolated as described previously. MLN cells ($2 \times 10^6$ cells/well) were incubated with immobilised anti-CD3 (5 μg/ml antimume CD3ε; BD Pharmingen, San Diego, California, USA) plus CD28 (2 μg/ml antimume CD28, BD Pharmingen) in 200 μl of complete medium containing $5 \times 10^{-5}$ M 2-mercaptoethanol (Sigma Chemical Co.) in a 5% CO$_2$ incubator at 37°C for 72 h. The supernatant of the culture medium was collected and stored at $-80°C$ until assayed.

**Isolation of colonic lamina propria macrophages**
Lamina propria macrophages were isolated using a modified protocol as described previously. Briefly, mice were sacrificed, and colonic tissues were removed, washed with cold PBS and cut into three pieces. The resected colonic tissues were shaken with Hank’s balanced salt solution (HBSS; Gibco) for 1 min at 2800 rpm in a Mini Bead Beater (Biospec Products, Bartlesville, Oklahoma, USA) to remove faeces and mucus, dissected into small pieces and then incubated with HBSS containing 5% fetal calf serum and 5 mM EDTA (Gibco) for 30 min at 37°C under rotation at 120 rpm. After washing, the pieces were incubated with complete RMI medium containing 1 mg/ml collagenase type II (Invitrogen, Carlsbad, California, USA), 1 mg/ml dispase (Gibco) and 40 μg/ml DNase (Roche, Mannheim, Germany) for 60 min at 37°C under rotation at 120 rpm to digest colonic tissues. After washing, the extracted cells were filtered and subjected to a magnetic cell separation system (Miltenyi Biotec, Auburn, California, USA) with antimouse CD11b microbeads to separate colonic lamina propria macrophages. Cell viability was determined by trypan blue staining, and >95% purity was confirmed by flow cytometry.

**ELISA**
The serum level of SR-PSOX/CXCL16 in the human subjects was determined quantitatively using a human CXCL16 immunoassay ELISA kit (R&D Systems). In the mouse model, the levels of SR-PSOX/CXCL16 in the serum and the supernatant of the colon fragment culture were measured using a mouse CXCL16 ELISA kit (R&D Systems). The cytokine levels of interleukin 6 (IL-6) and IL-12/25 p40 in the supernatants of the culture medium of thioglycollate-elicited peritoneal macrophage were measured using mouse ELISA kits (eBioscience, San Diego, California, USA). The secretions of IFNγ and IL-17 into the supernatants of culture medium in activated MLN cells were determined by mouse ELISA kits (eBioscience).

**Quantitative analysis of gene expression of SR-PSOX/CXCL16 in colonic tissue**
mRNA was assessed using colonic tissues isolated from the distal colon of WT mice with or without DSS-induced colitis. The extraction of total RNA, generation of cDNA and real-time reverse transcription–PCR (RT–PCR) were performed as described previously. The following primers were used: SR-PSOX/CXCL16, 5'-GGTCTTTGACCCCTTGTCTCTTG-3' (forward) and 5'-TTCCGCTAAACACATGCCTCAGCT-3' (reverse); and glyceraldehyde phosphate dehydrogenase (GAPDH), 5'-CAA CTTTGTCAAGCTCATTCCC-3' (forward) and 5'-GTCGCCAG GTTTTCTTACTCC-3' (reverse).

**Western blot analysis**
Colonic tissues were lysed in RIPA buffer (1% Triton X-100, 0.5% Na-deoxycholate, 0.1% sodium dodecyl sulfate (SDS), 20 mmol/l Tris–HCl (pH 7.4)) with protease inhibitor cocktail (Sigma Chemical Co.), and the insoluble material was removed by centrifugation at 12 000 g for 5 min at 4°C. The supernatants were boiled in sample buffer (0.05 mol/l Tris–HCl, 2% SDS, 6% β-mercaptoethanol, 10% glycerol, 1.25% bromophenol blue),
subjected to SDS–PAGE (10% polyacrylamide gels) and transferred onto polyvinylidine fluoride membranes (PALL Corporation, Pensacola, Florida, USA). The membranes were blocked with blocking buffer (Tris-buffered saline with 0.5% Tween-20 (TBS-T) containing 5% milk powder) and then incubated with a 1:1000 dilution of anti-CXCL16 mAb and with 1:5000 dilution

Figure 1  Serum levels of human SR-PSOX/CXCL16 are higher in patients with active inflammatory bowel disease (IBD). Serum samples were obtained from patients with active Crohn’s disease (CD) (n=14), inactive CD (n=16), active ulcerative colitis (UC) (n=16) and inactive UC (n=13), and from healthy controls (n=16). Results are expressed as means ± SEM. *p < 0.05 compared with control and **p < 0.05 between patients with active IBD and inactive IBD. (A) The statistical difference of serum SR-PSOX/CXCL16 in patients with IBD and healthy controls was determined by unpaired Student t test. (B) The relationship among serum SR-PSOX/CXCL16, C-reactive protein (CRP) and Crohn’s Disease Activity Index (CDAI) in patients with CD was assessed by the Pearson correlation coefficient test. (C) The relationship among serum SR-PSOX/CXCL16, CRP and Clinical Activity Index (CAI) in patients with UC was investigated by the Pearson correlation coefficient test or Spearman correlation test.
of anti-β-actin mAb (Sigma Chemical Co.) overnight at 4°C. The membranes were washed and incubated with a horseradish peroxidase (HRP)-conjugated IgG. The immunoreactive bands were visualised with Immobilon Western chemiluminescent HRP substrate (Millipore, Billerica, Massachusetts, USA), and the images were recorded using a chemiluminescent image reader (LAS-3000; Fujifilm, Tokyo, Japan).

Immunohistochemistry

For SR-PSOX/CXCL16 immunostaining, colonic tissues of WT mice with or without DSS-induced colitis, and Peyer’s patches as the positive control, were prepared as described previously. The sections were incubated with biotinylated anti-CXCL16 antibody (1:250; R&D Systems) or goat IgG isotype control overnight at 4°C. After washing, the sections were incubated with...
For immunofluorescence co-staining, cryosections (6 μm) of colonic tissue were fixed in cold acetone for 2 min and blocked with the Biotin Block system (DakoCytomation, Carpinteria, California, USA). Protein Block Serum-Free (DakoCytomation) and anti-CD11b/CD11c mAb (1:200; BD Pharmingen) and biotinylated anti-CXCL16 antibody (1:100; R&D Systems) or goat IgG isotype control overnight at 4°C. After quenching, the sections were incubated with streptavidin–HRP (1:1000). The signals were enhanced using the TSA biotin system (PerkinElmer) according to the manufacturer’s protocol and finally visualised by Alexa 594-conjugated streptavidin (1:2000; Invitrogen).

Furthermore, to evaluate the difference in cells recruited to colonic tissues of SR-PSOX/CXCL16 KO and WT mice with or without DSS-induced colitis, colonic tissues were incubated with FITC-conjugated anti-CD11b mAb (1:200; BD Pharmingen) and biotinylated anti-CXCL16 antibody (1:1000; R&D Systems) or goat IgG isotype control overnight at 4°C. After quenching, the sections were incubated with streptavidin–HRP (1:1000). The signals were enhanced using the TSA biotin system (PerkinElmer) according to the manufacturer’s protocol and finally visualised by Alexa 594-conjugated streptavidin (1:2000; Invitrogen).

Statistical analysis
All numerical data are expressed as means±SEM. The differences between groups were analysed by unpaired Student t test, Mann–Whitney U test and analysis of variance (ANOVA) for repeated measures. Parametric and non-parametric correlation was examined by the Pearson correlation coefficient test and the Spearman correlation test, respectively. The cumulative survival rate was calculated by the Kaplan–Meier method, and survival curves were compared by log-rank test. A p value <0.05 was considered significant.

RESULTS
Serum levels of SR-PSOX/CXCL16 increase in patients with active IBD
The serum levels of SR-PSOX/CXCL16 were significantly higher in patients with active CD and UC than in control subjects. The serum levels of SR-PSOX/CXCL16 were also significantly higher in patients with active CD and UC than in those with inactive CD and UC, respectively (figure 1A). Also, the serum levels of SR-PSOX/CXCL16 significantly correlated with clinical activities of both CD and UC (CADI and CAI; figure 1B,C). Considering the relationship among SR-PSOX/CXCL16, C-reactive protein (CRP) and clinical activities in CD and UC, SR-PSOX/CXCL16 might be a more suitable marker reflecting the disease activity of CD compared with that of UC.

SR-PSOX/CXCL16 plays a role in phagocytosis of bacterial components
SR-PSOX/CXCL16 is reported to be a chemokine expressed specifically on APCs such as macrophages and dendritic cells.11–13 In particular, we focused on macrophages that play a critical role in the uptake of luminal antigens and examined the ability of macrophages from SR-PSOX/CXCL16 KO and WT mice to phagocytose bacteria ex vivo. Fluorescence microscopy showed that the uptake of E coli by macrophages from both SR-PSOX/CXCL16 KO mice and WT mice increased in a time-dependent manner (figure 2A). Measurement of fluorescence intensity revealed that the fluorescence value was significantly lower from 60 to 120 min in SR-PSOX/CXCL16 KO macrophages than in WT macrophages (figure 2B).

SR-PSOX/CXCL16 is involved in the production of IL-12 by macrophages
To compare cytokine production by macrophages between SR-PSOX/CXCL16 KO and WT mice, we measured the levels of IL-6 and IL-12/23 p40 in the supernatant from macrophages of mice stimulated with LPS or CBL after pretreatment with IFNγ. There was no difference in the production of IL-6 by macrophages between SR-PSOX/CXCL16 KO and WT mice. In contrast, the production of IL-12/23 p40 by macrophages was

![Figure 3 SR-PSOX/CXCL16 levels are higher in mice with dextran sulfate sodium (DSS)-induced colitis. (A) The serum levels of SR-PSOX/CXCL16 in mice with DSS-induced colitis on day 8 and control mice were measured by ELISA. (B) The gene expression of SR-PSOX/CXCL16 in colonic tissues with or without DSS-induced colitis was determined by quantitative real-time reverse transcription–PCR (RT–PCR) and was normalised to glyceraldehyde phosphate dehydrogenase (GAPDH). (C) The production of SR-PSOX/CXCL16 in colonic tissues with or without DSS-induced colitis was investigated by western blot analysis. (D) SR-PSOX/CXCL16 concentrations in supernatants of colon fragment cultures were measured by ELISA. The results are expressed as means±SEM (n=10 in each group). (A), (B) and (D) Statistical difference was determined by unpaired Student t test. *p<0.05 and **p<0.01 between mice with DSS-induced colitis and normal controls.](http://gut.bmj.com/content/60/14/1494/figure/3)
significantly lower in SR-PSOX/CXCL16 KO mice than in WT mice (figure 2C). We also observed a significant difference in IL-12/23 p40 production by macrophages between SR-PSOX/CXCL16 KO and WT mice even without pretreatment with IFNγ (data not shown).

**Expression of SR-PSOX/CXCL16 increases in mice with DSS-induced colitis**

Next, we investigated the in vivo expression of SR-PSOX/CXCL16 in the DSS-induced colitis model. The serum levels of SR-PSOX/CXCL16 were significantly higher in mice with DSS-induced colitis than in normal controls (figure 3A). To examine whether the expression of SR-PSOX/CXCL16 increases in inflamed tissues, we analysed the colonic tissues of mice with or without DSS-induced colitis. The gene expression of SR-PSOX/CXCL16 was significantly higher in colonic tissues of DSS-induced colitis than in normal colon (figure 3B). Western blot analysis and ELISA also revealed that SR-PSOX/CXCL16 expression was significantly higher in colonic tissues of DSS-induced colitis than in normal colon (figure 3C,D).

To identify the cells that mainly express SR-PSOX/CXCL16 in colonic tissues, we performed immunohistochemical analysis and immunofluorescent co-staining. The follicular-associated epithelia of Peyer’s patches, used as a control, were positive for SR-PSOX/CXCL16, as reported previously (figure 4A, right upper panel). SR-PSOX/CXCL16-expressing cells were increased markedly in colonic tissues of mice with DSS-induced colitis compared with normal colons, and these cells were observed from the mucosa to the submucosa (figure 4A, right lower panel). Immunofluorescent images revealed that SR-PSOX/CXCL16-expressing cells were mainly CD11b-positive cells (figure 4B).

**Activity of DSS-induced colitis is reduced in SR-PSOX/CXCL16 KO mice**

To investigate the role of SR-PSOX/CXCL16 in colonic inflammation, we compared SR-PSOX/CXCL16 KO and WT mice with DSS-induced colitis. Before the analysis, we confirmed that there was no difference in the subsets of lymphocytes between SR-PSOX/CXCL16 KO mice and WT mice in the static state (Supplementary figure 1 online). The amount of body weight...
Figure 5  Activity of dextran sulfate sodium (DSS)-induced colitis is lower in SR-PSOX/CXCL16 knockout (KO) mice. (A) Serial change in body weight in SR-PSOX/CXCL16 KO and wild-type (WT) mice with or without 3% DSS-induced colitis. Data are expressed as the percentage change from the starting body weight. (B) Representative image and colonic length in SR-PSOX/CXCL16 KO and WT mice with or without 3% DSS-induced colitis on day 8. (C) Representative histological findings and the scores of colonic inflammation of SR-PSOX/CXCL16 KO and WT mice with or without 3% DSS-induced colitis on day 8. Scale bars, 100 μm. (D) Colonic tissues of SR-PSOX/CXCL16 KO and WT mice with or without 3% DSS-induced colitis were incubated with fluorescein isothiocyanate (FITC)-conjugated CD3, CD11b and CD11c, followed by nuclear counterstaining with 4’,6-diamidino-2-phenylindole (DAPI). Scale bars, 100 μm. (E) Fluorescent in situ hybridization analysis was performed with colonic tissues of SR-PSOX/CXCL16 KO and WT mice with or without 3% DSS-induced colitis using eubacterial oligonucleotide probe EUB-338 (red), followed by DAPI (blue). Scale bars, 50 μm (left two lanes) and 20 μm (right lane). (F) Colonic macrophages from SR-PSOX/CXCL16 KO and WT mice were subjected to an ex vivo phagocytosis assay against bacteria. Scale bars, 25 μm. (G) MLN cells from SR-PSOX/CXCL16 KO and WT mice on days 0, 5 and 8 after administration of 3% DSS were cultured with immobilised anti-CD3 plus CD28. Supernatants were collected after 72 h and subjected to ELISA to measure the concentration of interferon-γ (IFN-γ) and interleukin 17 (IL-17). (A)–(D), (F) and (G) The results are expressed as means ± SEM (n=10–12 in each group). The statistical comparison was assessed by repeated measure analysis of variance followed by unpaired Student t test (A) and (F). The statistical difference was determined by unpaired Student t test (B), (D) and (G) or Mann–Whitney U test (C). *p<0.05 and **p<0.01 between SR-PSOX/CXCL16 KO mice and WT mice with DSS-induced colitis.
**Intestinal inflammation**

loss was significantly less in SR-PSOX/CXCL16 KO mice than in WT mice from 6 to 8 days after DSS administration (figure 5A). The colon was significantly longer in SR-PSOX/CXCL16 KO mice with DSS-induced colitis than in WT mice with DSS-induced colitis (figure 5B). The histological findings on day 8 after DSS administration in WT mice revealed severe epithelial destruction, remarkable infiltration of inflammatory cells with submucosal oedema, and crypt loss (figure 5C, right upper panel). In contrast, these findings were mild in SR-PSOX/CXCL16 KO mice (figure 5C, right lower panel). The total colitis score was significantly lower in SR-PSOX/CXCL16 KO mice with DSS-induced colitis than in WT mice with DSS-induced colitis (figure 5C). Furthermore, fluorescent immunohistochemistry showed that the numbers of CD11c- and CD3-positive cells were significantly lower in colonic tissues of SR-PSOX/CXCL16 KO mice with DSS-induced colitis than in WT mice with DSS-induced colitis, despite no significant difference of the number of CD11b-positive cells between these two groups (figure 5D).

**SR-PSOX/CXCL16 is involved in bacterial invasion and phagocytosis of bacterial components in inflamed colonic tissues**

FISH with a universal oligonucleotide probe was performed to elucidate the difference in bacterial invasion of colonic tissues between SR-PSOX/CXCL16 KO and WT mice with/without colitis. FISH analysis showed that fewer bacteria invaded colonic tissues in SR-PSOX/CXCL16 KO mice with colitis compared with WT mice with colitis (figure 5E). Additionally, we investigated the phagocytic activity of colonic macrophages. Similar to the data with peritoneal macrophages, the fluorescence value was significantly lower from 60 to 180 min in SR-PSOX/CXCL16 KO colonic macrophages than in WT colonic macrophages (figure 5F).

**SR-PSOX/CXCL16 is related to the Th1 but not Th17 immune response in DSS-induced colitis**

Next, we measured cytokine production by MLN cells from both SR-PSOX/CXCL16 KO and WT mice with DSS-induced colitis. The production of IFNγ on day 5 after DSS administration was significantly lower in SR-PSOX/CXCL16 KO mice than in WT mice (figure 5G). In contrast, the production of IL-17 did not differ significantly between SR-PSOX/CXCL16 KO and WT mice with DSS-induced colitis throughout the experiment (figure 5G).

**Administration of SR-PSOX/CXCL16 mAb attenuates experimental murine colitis**

To assess the neutralising effect of a mAb to SR-PSOX/CXCL16 in mice with colonic inflammation, we analysed two experimental murine colitis models: DSS-induced colitis as an epithelial injury model and TNBS-induced colitis as a Th1-mediated colitis model. The body weight of mice with DSS-colitis treated with control IgG decreased and reached the lowest level on day 9, and gradually increased thereafter, although complete recovery was not obtained even on day 14. In contrast, in mice treated with SR-PSOX/CXCL16 mAb the body weight...
decreased to the lowest level on day 7 and recovered to a level similar to that before DSS administration on day 14. The body weight of mice treated with SR-PSOX/CXCL16 mAb was significantly higher from day 7 to 14 than that of IgG-treated control mice (figure 6A). Furthermore, administration of SR-PSOX/CXCL16 mAb significantly attenuated the shortening of colonic length (figure 6B), and significantly reduced colonic damage and the colitis score of mice with DSS-induced colitis on both day 8 and day 14 (figure 6C).

In addition, in TNBS-induced colitis, administration of SR-PSOX/CXCL16 mAb significantly ameliorated the body weight change on day 4 (figure 7A). Histological findings showed severe epithelial destruction, marked infiltration of inflammatory cells with mucosal oedema and remarkable loss of cryptal cells in control IgG-treated mice. In contrast, these colonic inflammatory findings were attenuated in SR-PSOX/CXCL16 mAb-treated mice. The colitis score was significantly lower in SR-PSOX/CXCL16 mAb-treated mice than in control IgG-treated mice (figure 7B). Furthermore, the overall survival rate of mice with TNBS-induced colitis treated with SR-PSOX/CXCL16 mAb was significantly higher than that of control IgG-treated mice (78.7% vs 38.9%; p=0.04; figure 7C).

**DISCUSSION**

Recent genetic approaches for elucidating the pathogenesis of IBD revealed that abnormality of the genes related to the innate immune response by recognising and/or processing bacterial components is involved in the development of IBD. Kamada et al suggested that the abnormal response of intestinal macrophages to commensal bacteria results in chronic intestinal inflammation. Therefore, the control of the abnormal innate immune response of APCs to commensal bacteria is important in the treatment of IBD. Indeed, we showed that macrophage-targeting treatment ameliorates colonic inflammation in an experimental colitis model. Taken together, targeting molecules related to macrophages appears to be a promising approach for the treatment of IBD. SR-PSOX/CXCL16 may be one such candidate molecule, because it is mainly expressed in APCs.

First, we found that the serum level of SR-PSOX/CXCL16 was significantly higher in patients with active IBD as reported previously, and moreover that the level correlated with the disease activity in patients with IBD. Analysis of correlation between disease activity and SR-PSOX/CXCL16 or CRP suggests that the serum SR-PSOX/CXCL16 might be a suitable biomarker for evaluating disease activity of CD rather than UC.

Furthermore, we investigated the serum concentration and tissue expression of SR-PSOX/CXCL16 in mice with DSS-induced colitis. Similar to human IBD, the serum level of SR-PSOX/CXCL16 and its expression in colonic tissue was significantly higher in mice with DSS-induced colitis than in normal mice. In addition, SR-PSOX/CXCL16 was expressed mainly on CD11b-positive cells and markedly increased in the colonic mucosa of mice with DSS-induced colitis, although these cells were barely observed in the colonic mucosa under normal conditions. Previous reports have shown that several inflammatory cytokines including IFNγ, tumour necrosis factor α (TNFα) and IL-18 induce the expression of SR-PSOX/CXCL16. Thus, increased concentration of various inflammatory cytokines in the inflamed colonic mucosa may contribute to enhanced expression of SR-PSOX/CXCL16 on macrophages.

Next, to evaluate the role of SR-PSOX/CXCL16 in both macrophage phagocytic activity and cytokine production, we examined phagocytosis and bacteria stimulated-cytokine production in peritoneal macrophages from SR-PSOX/CXCL16 KO mice in vitro. Our data clearly demonstrated that both the phagocytic ability and IL-12 production of macrophages of...
SR-PSOX/CXCL16 KO mice was significantly impaired. Of note, LPS and CBL-induced IL-12 production was significantly reduced in SR-PSOX/CXCL16 KO mice in the presence of IFNγ. This appears reasonable, because IFNγ has been reported to enhance SR-PSOX/CXCL16 expression.49

The present study clearly showed that SR-PSOX/CXCL16 KO mice had reduced activity of DSS-induced colitis. Moreover, SR-PSOX/CXCL16 mAb ameliorated colitis in two different experimental models. These data indicate that SR-PSOX/CXCL16 plays important roles in the development of colitis. The DSS-induced colitis model is characterised by direct epithelial injury and subsequent activation of macrophages,35 and SR-PSOX/CXCL16 is reported to be involved in DSS-induced IL-1β production by macrophages.42 Therefore, the DSS-induced colitis model is suitable for investigating the interaction between luminal bacteria and macrophages expressing SR-PSOX/CXCL16. In our current study, SR-PSOX/CXCL16 was expressed predominantly on CD11b-positive cells at subepithelial sites of the inflamed colonic mucosa. In addition, we found that bacterial invasion of the lamina propria in the colitic mucosa was reduced in SR-PSOX/CXCL16 KO mice. SR-PSOX/CXCL16 has been reported to act as a scavenger receptor that mediates adhesion and phagocytosis of bacteria by APCs.14 In this connection, we demonstrated here that both peritoneal and intestinal macrophages of SR-PSOX/CXCL16 KO mice had reduced ability to phagocytose bacterial antigens. Taken together, our data suggest that SR-PSOX/CXCL16 exerts its colitogenic action at least in part by promoting bacterial uptake into macrophages in the colonic mucosa.

In this study, SR-PSOX/CXCL16 mAb also ameliorated TNBS-induced colitis, a Th1-mediated colitis model. An interesting finding in this study is that SR-PSOX/CXCL16 KO macrophages had an impaired ability to produce IL-12 in response to not only LPS but also commensal bacterial antigens, although their production of IL-6 was unaffected. Moreover, we observed that MLN cells from SR-PSOX/CXCL16 KO mice with DSS-induced colitis showed reduced production of IFNγ but not of IL-17. Because IL-6 is essential for the induction of Th17 cells, the lack of difference in IL-6 production by macrophages or IL-17 production by MLN cells between SR-PSOX/CXCL16 KO and WT mice suggests that SR-PSOX/CXCL16 is not involved in the Th17-mediated immune response. Taken together, our data indicate that SR-PSOX/CXCL16 plays a colitogenic role by enhancing the Th1 immune response. Of note, IL-17A had a protective role in the CD45RBlh transfer model of colitis and suppressed the induction of T-bet in maturing Th1 cells.43 Thus, targeting SR-PSOX/CXCL16 seems to be an ideal treatment for preventing Th1-mediated colitis, without affecting the IL-17-mediated immune response.

In conclusion, our present data clearly demonstrated that SR-PSOX/CXCL16 plays a critical role in the development of colonic inflammation probably by both activating uptake of commensal bacteria and enhancing the Th1 immune response. SR-PSOX/CXCL16 may be a therapeutic target for patients with IBD.

Left lower quadrant abdominal pain caused by an IUCD

**CLINICAL PRESENTATION**

A previously healthy 42-year-old woman presented with mild left lower quadrant abdominal pain. There was no relevant medical or family history except she had a T-shaped copper intrauterine contraceptive device (IUCD) inserted 10 years previously. The remainder of her obstetric history was non-specific and included one normal vaginal delivery. Physical examination and laboratory findings at the time of presentation were unremarkable.

Plain radiographs of the abdomen identified the IUCD in the pelvic cavity (figure 1); however, the IUCD was not detected during gynaecological ultrasonography. Further abdominal CT scanning did not reveal any definite focal lesions and the IUCD was not identified (figure 2).

**QUESTION**

What is your diagnosis?

What additional tests are indicated and how should the patient be managed?

See page 1562 for the answer

**Figure 1** Plain abdominal radiograph showed the T-shaped intrauterine contraceptive device (IUCD) in the left pelvic cavity. The surrounding fat planes to the uterus were identified (arrows) and the device appeared separate from the fat planes.

**Figure 2** Contrast-enhanced CT scan using the soft tissue window setting did not identify any definite focal lesions.
SR-P Sox/CXCL16 plays a critical role in the progression of colonic inflammation
