Running Title:

MRI protocol for molecular imaging by a pre-targeting method

Manuscript category

Article
ABSTRACT (~ 150 words)

Purpose

We aimed to establish a magnetic resonance imaging (MRI) protocol for the sensitive and specific imaging of functional molecules with a pre-targeting strategy utilizing the streptavidin-biotin interaction. Membrane type-1 matrix metalloproteinase (MT1-MMP) was selected as the target molecule.

Procedures

The biotinylated polyamidoamine dendrimer (PAMAM)-based contrast agent (Bt-PAMAM-DTPA(Gd)) was prepared, and its proton relaxivity ($r_1$) and affinity to streptavidin were evaluated. Tumor-bearing mice were pre-targeted with streptavidin-conjugated anti-MT1-MMP monoclonal antibody (mAb), streptavidin-conjugated negative control IgG, or saline and 3 days later were injected with Bt-PAMAM-DTPA(Gd) followed immediately by MRI for a period of 3 h.

Results

High $r_1$ (15.5 L mmol$^{-1}$ s$^{-1}$) and 1.9-fold higher affinity than D-biotin were obtained. Significantly higher relative tumor signals were observed in mice pre-targeted with streptavidin-conjugated anti-MT1-MMP mAb (165% at 3 h vs. pre-administration) than with saline or streptavidin-conjugated negative control IgG ($P < 0.0001$).

Conclusions
This pre-targeting approach can accomplish sensitive and specific \textit{in vivo} MRI of functional molecules.

INTRODUCTION

Magnetic resonance imaging (MRI), characterized by a remarkable spatial resolution, is a powerful tool for noninvasive morphologic diagnosis of diseases including cancer. Recently, the application of MRI to functional molecular imaging coupled with anatomical information has been explored. To realize functional molecular imaging by MRI, contrast agents are required that possess a high relaxation to produce high MR signals to compensate for the low intrinsic sensitivity of MRI [1] in addition to selectively accumulating in the targeting site.

Gadolinium (Gd) chelates conjugated to macromolecules such as liposomes, micelles and dendrimers can give rise to enhanced proton relaxivities in comparison with simple, small molecule contrast agents such as Gd-diethylenetriamine pentaacetic acid (Gd-DTPA) [2-4]. This effect is due to a restriction in thermal flexibility leading to increased interactions between the Gd atom and surrounding water molecules [5-7]. Some groups have developed monoclonal antibody (mAb)-conjugated macromolecular contrast agents for imaging integrin αvβ3 or human epidermal growth factor receptor type 2 (HER2) in tumors, which successfully increased the tumor signal intensity by 15-30% [8, 9]. However, many researchers have failed to demonstrate in vivo functional molecular imaging using macromolecules conjugated with several Gd chelates and targeting moieties like antibodies and peptides because the pharmacokinetics of the targeting moieties were significantly altered.
by the introduction of macromolecular contrast agents, which resulted in low target recognition and high accumulation of the labeling agent in non-targeted tissues [10, 11]. Furthermore, when antibody-conjugated macromolecular contrast agents are injected at a Gd dose (0.1 mmol Gd/kg) necessary for adequate imaging, excess antibody (on the order of milligrams per mouse) are typically administered, which leads to major limitations of cost and \textit{in vivo} toxicity.

Thus, in this study, to overcome these problems and to realize functional molecular MRI by a macromolecule-based contrast agent, we aimed to use a pre-targeting strategy that utilizes the high affinity interaction between streptavidin and biotin ($K_d=10^{-15}$ M) [12]. In this pre-targeting method, the first step is to administer a streptavidin-conjugated target-specific antibody. In the second step, after selective accumulation of streptavidin-conjugated antibody in the targeted tissue and clearance of unbound targeting agent from the circulation, a biotin-bound imaging probe is injected. As the post-administration contrast agent, polyamideamine dendrimer (PAMAM) was selected as the base structure since it is structurally well-defined and functional moieties including biotins and Gd chelates for both targeting and signal emission functions can easily be attached to the large number of its surface amino groups. The pre-targeting strategy is expected to provide selective and effective accumulation of the PAMAM-based contrast agent to the targeted site and a high S/N ratio during the first hours following administration as has been observed in
radioimmunotherapy and radioimmunodetection [13-16], and to potentially lead to lower in vivo toxicity [17, 18].

Thus, in this paper we describe our efforts to establish a sensitive and specific in vivo MRI protocol for imaging functional molecules utilizing a pre-targeting strategy that combines a streptavidin-conjugated antibody with a PAMAM based contrast agent modified with biotins. As the targeted biomolecule, membrane type-1 matrix metalloproteinase (MT1-MMP) was selected. Since MT1-MMP is exclusively expressed in tumors and is closely associated with metastasis [19] and invasion [20], MT1-MMP is a potential imaging target for evaluation of tumor malignancy.
MATERIALS AND METHODS

Synthesis of streptavidin-conjugated anti-MT1-MMP mAb

Streptavidin-conjugated anti-MT1-MMP mAb and streptavidin-conjugated negative control IgG were synthesized according to a previously described method [14]. Briefly, EZ-Link® sulfosuccinimidyl-6-(biotinamido) hexanoate (sulfo-NHS-LC-biotin) (Pierce, Inc.) was added to a solution of anti-MT1-MMP mAb (113-5B7, Daiichi Fine Chemical Co.) in a molar ratio of 12:1. The mixture was gently stirred for 30 min at room temperature and then was purified with a diafiltration membrane (Amicon Ultra 4 (MWCO 30,000), Millipore Co.). A solution of biotinylated anti-MT1-MMP mAb was added to a solution of streptavidin (SAv; Pierce, Inc.) in a 1:3 molar ratio. The mixture was incubated for 1 h at 37 °C followed by purification twice by affinity chromatography using a HiTrap rProtein A column (GE Healthcare Bioscience). The eluate containing anti-MT1-MMP mAb-SAv was concentrated with a diafiltration membrane (MWCO 30,000), and the protein concentration was determined by the bicinchoninate (BCA) method. The purification was monitored by a size exclusion chromatograph using a 300×4.6-mm i.d. TSK-Gel Super SW 3000 column (Tosoh Co., Japan) eluted with phosphate buffer (0.1 M, pH 6.8) at a flow rate of 0.1 mL/min. Comparison of molecular mass standards (Oriental Yeast Co., Japan) of the absorbance at 280 nm indicated that a peak at 30.3 min was consistent with the presence of the 210 kDa streptavidin-conjugated anti-MT1-MMP mAb. Furthermore, streptavidin-conjugated
anti-MT1-MMP mAb retained 81.3% immunoreactivity of the anti-MT1-MMP mAb, which was confirmed by flow cytometry.

**Synthesis of Bt-PAMAM-DTPA(Gd)**

EZ-Link® sulfo-NHS-LC-biotin was added to a solution of PAMAM (generation 4 (G4)) (Sigma Aldrich) in a molar ratio of 20:1. The mixture was stirred for 30 min at room temperature and then was applied to a diafiltration membrane (MWCO 10,000) to remove unbound biotins as well as to change the buffer to phosphate buffer (0.1 M, pH 9.0). After purification, the incorporation ratio of biotins conjugated to each dendrimer was measured using an EZ™ Biotin Quantitation Kit (Pierce, Inc.). The biotinylated PAMAM was reacted with a 64-fold molar excess of 2-(p-isothiocyanatobenzyl)-diethylenetriaminepentaacetic acid (p-SCN-Bz-DTPA) (Macrocyclics) at 40°C for 24 h. During the reaction, the pH was maintained at 9.0 with 1 N NaOH. An additional equal amount of p-SCN-Bz-DTPA was added after 24 h and the reaction was incubated for another 24 h at 40°C. The resulting preparation was purified by diafiltration membrane (MWCO 10,000). After purification, the number of DTPAs incorporated into each G4 dendrimer was checked by chelate titration using ZnSO₄ (indicator: 4-(2-pyridylazo)resorcinol, NH₃/NH₄⁺, pH 10) according to a previously described method with some modification [21]. Purified Bt-PAMAM-DTPA was mixed with GdCl₃ (Sigma Aldrich) in citrate buffer (0.3 M, pH 5.0) for 2 h at 40°C. The
excess Gd was removed by diafiltration membrane (MWCO 10,000) while simultaneously changing the buffer to PBS (0.1 M, pH 7.4). The number of Gd incorporated into a dendrimer was checked by separating the free Gd and Bt-PAMAM-DTPA(Gd) with diafiltration filter after labeling the Bt-PAMAM-DTPA with $^{153}$Gd and nonradioactive Gd. For comparison purposes, PAMAM-DTPA(Gd) containing one biotin ($\text{Bt}_1$-PAMAM-DTPA(Gd)) was also prepared in a similar manner.

Stability of Bt-PAMAM-DTPA(Gd) in mouse plasma

$^{153}$Gd-labeled Bt-PAMAM-DTPA(Gd) was prepared by reacting Bt-PAMAM-DTPA(Gd) with $^{153}$Gd (1 μCi, PerkinElmer Japan Co., Osaka, Japan) and non-radioactive Gd in 0.3 M citrate buffer at pH 5.0 for 2 h at 40°C. $^{153}$Gd labeled Bt-PAMAM-DTPA(Gd) (30 μL) was added to mouse plasma collected from female C3H/He mice (270 μL), and the plasma samples were incubated at 37°C for 0, 3, and 24 h. After incubation, aliquots of the samples were drawn, and radioactivity was analyzed by size-exclusion chromatography with a PD-10 column (GE Healthcare Bioscience) using saline as eluent.

Affinity of Bt-PAMAM-DTPA(Gd) for streptavidin

Competition assays of $^{125}$I-(3-iodobenzoyl)norbiotinamide ($^{125}$I-IBB), a radiolabeled
biotin derivative synthesized as reported previously [22], were performed by incubating streptavidin (Pierce, Inc.; 400 μL, 2 μg/mL), $^{125}$I-IBB (50 μL, 5 μCi), and various concentrations of Bt-PAMAM-DTPA(Gd), Bt$_1$-PAMAM-DTPA(Gd), and D-biotin (Nacalai Tesque, Kyoto, Japan) (50 μL, $10^{-8}$~$10^{-4}$ M) in PBS (0.1 M, pH 7.4) for 60 min at 37°C. At the end of the incubation, the mixture was applied to a size exclusion column with a Sephadex G-50 Fine (GE Healthcare Bioscience), followed by measurement of the radioactivity from the column eluent (containing macromolecules) with a NaI well-type scintillation counter (1470WIZARD, PerkinElmer Japan Co.). Nonspecific binding was determined in the presence of 10 mg/mL D-biotin. The 50% inhibitory concentrations (IC$_{50}$s) were determined from displacement curves of the percent inhibition of $^{125}$I-IBB binding vs. the inhibitor concentration.

Preparation of tumor-bearing animals

Female C3H/He mice (5 weeks old), supplied by Japan SLC Co. (Hamamatsu, Japan), were housed under a 12-h light/12-h dark cycle and were given free access to food and water. The animal experiments in this study were conducted in accordance with institutional guidelines and were approved by the Kyoto University Animal Care Committee, Japan.

FM3A mouse breast carcinoma cells were supplied by the Health Science Research Resources Bank (Osaka, Japan). They were cultured in DMEM medium (Nissui
Pharmaceutical Co.) supplemented with 10% fetal bovine serum at 37°C in a humidified atmosphere containing 5% CO₂ and 95% air and had a 10.6-h doubling time.

FM3A cells were suspended in 0.01 M PBS (pH 7.4) followed by subcutaneous inoculation into the right hind leg of the mouse (5 × 10⁶ cells/100 μL/mouse) [23]. The tumor volume was estimated by (length)×(width)²/2 [24] over a 10-day tumor growth period. The average size of the tumors was 213 ± 82 mm³ on the MR imaging study day. The expression of MT1-MMP in FM3A cells and tumor tissues was confirmed by western blotting and immunohistochemistry [25].

**Magnetic Resonance Imaging**

MRI was performed using a clinical 1.5 Tesla MR scanner (MAGNETOM Symphony Sonata, Siemens). All T₁-weighted MR images were acquired with a multislice spin-echo pulse sequence. MRI data were analyzed using the ImageJ software.

**Phantom study**

Solutions of Gd-DTPA (Sigma Aldrich) and Bt-PAMAM-DTPA(Gd) were prepared with a Gd concentration in the range of 10 to 500 μM in vials with an inner diameter of 15 mm followed by the MR scan using a knee coil (20.5 cm in diameter) at 20°C. To obtain proton relaxivity (r₁) for samples, spin-echo images were obtained using a sequence with TR=500, 1000, 1500, and 2000 msec and with TE=15 msec. The imaging parameters were as
follows: field-of-view, 256×128 mm; matrix, 256×128; slice thickness, 7 mm; number of average, 3.

In vivo study

Mice (n=4) bearing FM3A tumors in the right thigh received streptavidin-conjugated anti-MT1-MMP mAb (50 μg/100 μL in saline) via tail vein. Three days later, Bt-PAMAM-DTPA(Gd) (0.1 mmolGd/kg, 100 μL in PBS (0.1 M, pH 7.4), i.v.) was injected followed by data acquisition by MRI at several time points over a 3-h post-injection period under sodium pentobarbital (50 mg/kg, i.p.) anesthesia. All MR images were obtained using a hand-made round surface coil (5.5 cm in diameter) fixed by a custom constructed coil holder. The imaging parameters were as follows: TR/TE, 300/5.2 msec; field-of-view, 128×96 mm; matrix, 256×192; slice thickness, 1.5 mm; number of average, 3. MRI studies were also conducted as above on FM3A tumor bearing mice (n=3) pre-treated with saline (100 μL) or streptavidin-conjugated negative control IgG (50 μg/100 μL in saline). The signal intensity was calculated by drawing a region of interest around the tumor, muscle in the contralateral hind limb, and kidneys. The relative signal intensity in each tissue was defined as the signal intensity after administration of Bt-PAMAM-DTPA(Gd) divided by the signal intensity before administration.

Statistical Analysis
Unpaired Student’s t test was used to evaluate the significance of differences of $r_1$ between Bt-PAMAM-DTPA(Gd) and Gd-DTPA. To compare the time courses of relative signal intensity in the tumor and kidneys and tumor/muscle (T/M) signal ratios among Bt-PAMAM-DTPA(Gd) pre-targeted by streptavidin-conjugated anti-MT1-MMP mAb, streptavidin-conjugated negative control IgG, and saline, two-way repeated measures ANOVA with post-hoc analysis by the Tukey-Kramer test was performed. Differences at the 95% confidence level ($P < 0.05$) were considered significant.
RESULTS

Characterization of Bt-PAMAM-DTPA(Gd)

Bt-PAMAM-DTPA(Gd) was synthesized in four steps from PAMAM in a yield of 63%. PAMAM was conjugated to 9.9 ± 1.3 biotins and 43.6 ± 1.9 DTPAs, which were quantitatively coordinated to Gd. Bt₁-PAMAM-DTPA(Gd) containing 1.0 ± 0.1 biotin and 47.6 ± 2.2 DTPAs on PAMAM dendrimer was also synthesized. The $^{153}$Gd-labeled Bt-PAMAM-DTPA(Gd), which was incubated with mouse plasma for 24 h, did not release any low molecular weight metabolites or free radiometals (Fig. 1).

The competitive binding assay revealed that all of the contrast agents inhibited the binding of $^{125}$I-IBB to streptavidin in a dose-dependent manner (Fig. 2). The IC₅₀s for Bt-PAMAM-DTPA(Gd), Bt₁-PAMAM-DTPA(Gd), and D-biotin were 32 ± 31, 1390 ± 1220, and 60 ± 45 nM, respectively, demonstrating that Bt-PAMAM-DTPA(Gd) had about 1.9- and 43.2-fold higher affinity to streptavidin than D-biotin and Bt₁-PAMAM-DTPA(Gd).

MR imaging study (Phantom study)

The in vitro $T₁$-weighted MR images with Bt-PAMAM-DTPA(Gd) and Gd-DTPA are shown in Fig. 3a. Water and PBS were used as baselines. With the same Gd concentration, the signals with Bt-PAMAM-DTPA(Gd) were higher compared to Gd-DTPA. The longitudinal relaxation rate ($1/T₁$) vs. the concentration of Gd for both contrast agents are
shown in Fig. 3b with good linear fits ($R^2 = 1.00$ and 0.99 for Bt-PAMAM-DTPA(Gd) and Gd-DTPA, respectively). Calculated $r_1$ values (L mmol$^{-1}$ s$^{-1}$) for Bt-PAMAM-DTPA(Gd) and Gd-DTPA were $15.5 \pm 1.1$ and $3.6 \pm 0.1$, respectively, which shows that the proton relaxivity of Bt-PAMAM-DTPA(Gd) was 4.3-fold higher than that of Gd-DTPA ($P < 0.0001$).

**MR imaging study (in vivo study)**

Figure 4a (coronal) and 4b (transaxial) show in vivo $T_1$-weighted MR images of tumor-bearing mice before and at 5 min and 180 min after injection of Bt-PAMAM-DTPA(Gd) following pre-treatment with streptavidin-conjugated anti-MT1-MMP mAb (MT1-MMP), streptavidin-conjugated negative control IgG (Negative Control), or saline (Saline). In the MT1-MMP group, the most intense signal was observed in the margin of the tumor, as compared with the tumor core, over the 180-min period. The relative signal intensity (rSI) in the tumor and the relative T/M ratio were strongly enhanced just after administration of Bt-PAMAM-DTPA(Gd) and were highly maintained for 3 h after the contrast agent injection as well as the rapid clearance from the circulation (Fig. 4c, d). These signals were significantly greater than those from the Negative Control group ($P < 0.05$ (at 44 and 55 min), $P < 0.01$ (at 2 and 3 h)). In the Saline group, Bt-PAMAM-DTPA(Gd) readily disappeared from the circulation and mainly accumulated in the kidneys. Though the relative signal intensity in the tumor also increased (190%) just after administration of
Bt-PAMAM-DTPA(Gd), it decreased to the basal level (115%) within 3 h (Fig. 4c). A slightly higher tumor signal was obtained in the Negative Control group than in the Saline group only 3 h after injection of Bt-PAMAM-DTPA(Gd) (P < 0.01). The time-dependent change of relative T/M ratios was similar to that of the relative signal intensity in the tumor (Fig. 4d). The time-dependent change of relative signal intensity in the kidneys was very similar in all three groups (Fig. 4e).
DISCUSSION

In this study, we accomplished visualization of MT1-MMP by MRI using a pre-targeting method with a PAMAM-based contrast agent (Bt-PAMAM-DTPA(Gd)) which possesses high proton relaxivity and high affinity to streptavidin. For future applications, this pre-targeting method based on the interaction between biotin and streptavidin is promising for the detection of functional molecules, such as biomarkers in tumors like MT1-MMP, by in vivo MRI.

Although several macromolecular contrast agents have been developed for functional molecular imaging with MRI using a mAb or peptide as the targeting moiety, these attempts have been largely unsuccessful because the macromolecular contrast agents, such as an antibody attached to a dendrimer, have a poorer targeting ability and slower pharmacokinetics in the circulation than the targeting moiety alone, which leads to an inadequately low S/N ratio for several days post-injection [10, 11]. Thus, we focused on a pre-targeting strategy whose effectiveness in elevating the S/N ratio shortly after injection has been well documented in the field of radioimmunotherapy [13, 26]. In the pre-targeting strategy, high affinity between the pre- and post-administered agents is required; thus, the affinity of a post-administered biotinylated contrast agent to streptavidin needed to be evaluated. In this study, Bt-PAMAM-DTPA(Gd) containing approximately 10 biotins in the structure showed 43.2- and 1.9-fold higher affinity to streptavidin compared with Bt₁-PAMAM-DTPA(Gd)
containing only one biotin per dendrimer and D-biotin, respectively, which suggests a multivalent effect of Bt-PAMAM-DTPA(Gd) binding to streptavidin. Zhu et al. recently reported the MRI of functional molecules by a pre-targeting approach [27]; however, the authors failed to show a significant tumor image probably because of the small number of biotins per dendrimer (≈4 biotins per dendrimer). Therefore, in a pre-targeting method where a macromolecule is used as the post-administered agent, it is essential that an optimal number of biotins on the macromolecule is evaluated.

In the streptavidin-conjugated anti-MT1-MMP mAb-treated group, MR signals in the tumor and T/M ratios were highly maintained following Bt-PAMAM-DTPA(Gd) administration compared with the saline-treated group, which suggests that the tumor accumulation of Bt-PAMAM-DTPA(Gd) depended on the pre-targeted streptavidin-conjugated anti-MT1-MMP mAb. Furthermore, MR signals in the tumor and T/M ratios were also significantly higher in the streptavidin-conjugated anti-MT1-MMP mAb-treated group than those in the negative control, which suggests that the accumulation of Bt-PAMAM-DTPA(Gd) was primarily specific for MT1-MMP. The slightly significant difference in the relative tumor signal was shown between negative control and saline group is probably caused in part by passive accumulation of the pre-targeted streptavidin-conjugated antibody as a macromolecule due to an enhanced permeability and retention effect [28].
Previously, to determine the optimal interval between injections of streptavidin-conjugated anti-MT1-MMP mAb and Bt-PAMAM-DTPA(Gd), the biodistribution of $^{125}$I-labeled streptavidin-conjugated anti-MT1-MMP mAb was evaluated in C3H/He mice bearing FM3A mouse breast carcinoma [14]. From consideration of the high accumulation of streptavidin-conjugated antibody in the tumor and the high tumor to blood ratio at 72 h, we adopted this time as the interval between pre- and post-administrations in this study. Recently, some reports have shown that clearing agents (e.g. galactosylated biotin-albumin conjugate) can readily (within a few hours) clear surplus streptavidin conjugated antibody in the circulation to the liver where the complex is metabolized and excreted without loss of the biotin binding sites in the tumor [29-31], thereby shortening the interval between injections. In the future, by taking advantage of this type of strategy, we can establish an optimal protocol for MT1-MMP imaging for clinical applications.

Dendrimers are a class of highly branched spherical polymers, with a variety of properties, such as chemical structure, size, molecular weight and functional groups that can be easily manipulated at the molecular level through their synthesis. The pharmacokinetics of the dendrimer is susceptible to control with its generation number such that it may be highly bioavailable, an important consideration for a variety of applications, especially in the biomedical field [32]. Here, PAMAM dendrimer was chosen as the base structure of the contrast agent for post-administration. PAMAM dendrimer (G4) with an ethylene diamine
core has a molecular weight of 14,215 Da and possesses 64 amino groups on the surface of
the molecule [33]. In this study, 10 biotins and 44 Gds for specific targeting and sensitive
imaging were introduced onto the dendrimer. An in vitro MR study showed that the relaxivity
of Bt-PAMAM-DTPA(Gd) was 4.3-fold higher than Gd-DTPA, which indicates the
effectiveness of Bt-PAMAM-DTPA(Gd) as a contrast agent with high proton relaxivity as
expected because of slow tumbling rates and a short water residence time [2, 5].

The post-administered contrast agent in a pre-targeting study should satisfy the
following two requirements besides specific affinity to pre-administered streptavidin: rapid
blood clearance and low nonspecific accumulation in the tumor. It has been reported that a
PAMAM (G4) dendrimer is quickly excreted via glomerular filtration primarily during the
first pass (the blood $\alpha$ phase half-life: 2.5 min, $\beta$ phase half-life: 35 min [34]), and not via the
bile pathway. In addition, these dendrimers exhibit no measurable leakage from normal blood
vessels because of their moderate size (ca 6 nm) [2, 34-37], which leads to low nonspecific
accumulation in the tumor caused by passive accumulation based on an enhanced
permeability and retention effect. PAMAM (G4)-based MR contrast agents can be effective
as imaging probes, as supported by the experimental data that showed low MR signals
observed in the tumors of the saline pre-targeted group while intense signals were observed in
the kidneys after the acute disappearance of Bt-PAMAM-DTPA(Gd) from the circulation.

As mentioned above, in the case of antibody-conjugated dendrimer-based contrast
agents, excess antibodies (on the order of milligrams per mouse) are typically administered when injected at a Gd dose (0.1 mmol Gd/kg) necessary for adequate imaging, which leads to major limitations of cost and toxicity. On the other hand, our pre-targeting strategy could control the amount of injected streptavidin-conjugated antibody by corresponding to the targeted molecule (about 50 μg per mouse for MT1-MMP), which would be useful for reducing the cost and toxicity of the imaging process.

In the application of dendrimers in vivo, cytotoxicity is often a major issue. To date, as has been widely demonstrated for other polycations, dendrimers bearing amino termini display concentration- and commonly generation-dependent cytotoxicity [38] and potent hemolytic activity [39]. These effects could be attributable to the electrostatic interactions of the positively charged dendrimer with the negatively charged cell membrane under physiological pH. Nevertheless, Bt-PAMAM-DTPA(Gd) used in this study was negatively charged due to modifications of the amino termini to bind biotin and DTPA such that it could be acceptable in vivo. This assertion is supported by a report that PAMAM dendrimers bearing carboxylate termini display dramatically lower toxicity to cells [40]. We also plan to acetylate or succinylate the free amino groups to further reduce the positive charge of the complexes if needed to decrease toxicity and hemolytic activity. The rapid excretion of Bt-PAMAM-DTPA(Gd) via glomerular filtration should alleviate adverse effects such as nephrogenic systemic fibrosis [41] derived from released Gd, as compared with
macromolecular contrast agents which have slow elimination pharmacokinetics [11, 42], although further analysis of the cytotoxicity is needed.
CONCLUSIONS

The pre-targeting method utilizing the specific interaction between streptavidin and biotin enabled the visualization of MT1-MMP expressing tumors by 1.5 T MRI with high S/N ratios during the first hours following administration of a contrast agent, Bt-PAMAM-DTPA(Gd). The results suggest that this method may be beneficial to diagnose tumor malignancy in a clinical setting. In future work, this method could be applied to the imaging of a variety of pathologic functional molecules expressed on cell surface.

(a, b) In vivo $T_1$-weighted MR images of C3H/He mice before and at 5 min and 180 min after injection of Bt-PAMAM-DTPA(Gd) following pre-treatment with streptavidin-conjugated anti-MT1-MMP mAb (MT1-MMP), streptavidin-conjugated negative control IgG (Negative control), or saline (Saline). The coronal (a) and transaxial (b) images are shown. Arrows or dotted squares indicate the tumor site. Enlarged images of the dotted square regions are also shown.

(c-e) The dynamic change of signal intensity in the tumor by Bt-PAMAM-DTPA(Gd) (c) and relative tumor to muscle ratios (d) following pre-treatment with streptavidin-conjugated anti-MT1-MMP mAb (MT1-MMP, circles), streptavidin-conjugated negative control IgG (Negative control, squares), or saline (Saline, crosses). (e) The dynamic change of signal intensity in the kidney for each animal group. *$P < 0.05$, §§$P < 0.01$ vs. Negative Control; †$P < 0.01$ vs. Saline; ‡$P < 0.01$ Negative Control vs. Saline
(a) Table showing Gd concentration (μM) and corresponding images:

<table>
<thead>
<tr>
<th>Gd concentration (μM)</th>
<th>Gd-DTPA</th>
<th>Bt-PAMAM-DTPA(Gd)</th>
<th>PBS, water</th>
</tr>
</thead>
<tbody>

</table>

(b) Graph showing $1/T_1$ vs. Gd concentration (mM):

- Bt-PAMAM-DTPA(Gd)
- Gd-DTPA

The graph shows a linear relationship between $1/T_1$ and Gd concentration for both Bt-PAMAM-DTPA(Gd) and Gd-DTPA.
