Abstract

Background: The roles of microphthalmia-associated transcription factor (Mitf) in the skeletal muscle and during myogenesis are unclear.

Methods: Expression of *Mitf* in mouse tissues and during myogenesis was evaluated. Effects of *Mitf* knockdown on myogenesis and gene expression related to myogenesis were subsequently explored. Furthermore, effects of *p21*, a cyclin-dependent kinase inhibitor, and *integrin α 9* (*Itga9*) were examined.

Results: Mitf was highly expressed in the skeletal muscle; *Mitf-A* and *-J* were expressed. Mitf expression increased after differentiation stimulation in C2C12 myogenic cells. Down-regulation of *Mitf* expression by transfection of siRNA for common *Mitf* inhibited myotube formation, which was reproduced by *Mitf-A* knockdown. Morphometric analyses indicated that both multinucleated cell number and the proportion of myotubes with more than 6 nuclei were decreased in *Mitf*-knockdown cells, suggesting that Mitf is required for not only the formation of nascent myotubes but also their maturation. Searching for genes positively regulated by Mitf revealed *p21* and *Itga9*; decreasing *Mitf* expression inhibited up-regulation of *p21* expression after differentiation stimulation and blocked the induction of *Itga9* expression in response to differentiation. Knockdown of *p21* decreased the number of multinucleated cells, whereas *Itga9* knockdown did not affect the myotube number. Both *p21* knockdown and *Itga9* knockdown decreased the proportion of myotubes with more than 6 nuclei.

Conclusion: The present study clarified that Mitf is significantly expressed during myogenesis, and that *Mitf* is required for efficient myotube formation through expression of *p21* and *Itga9*.

General significance: Mitf positively regulates skeletal muscle formation.

Keywords: Mitf, myogenesis, integrin, p21, myotube

Introduction

Skeletal muscle formation consists of a complex set of differentiation steps: commitment of mesenchymal stem cells to myoblast lineage cells, progression of differentiation with the expression of muscle-cell-specific proteins, and fusion of myoblasts into multinucleated myotubes. Mammalian myotube formation occurs in two phases [1, 2]. In the first phase, differentiated myoblasts fuse together to form small myotubes; to accomplish this process, proliferating myoblasts exit cell cycle, and some myoblasts undergo apoptosis. In the second phase, additional myoblasts subsequently fuse with myotubes to form large myotubes. Although the roles of myogenic regulatory factors (MRFs), including Myf5, Myod, Myogenin and Mrf4, in myogenic differentiation are unquestionable [3-5], a number of factors, such as secreted proteins, membrane proteins and transcriptional regulators, are also involved in myogenesis [2].

Microphthalmia-associated transcription factor (Mitf) is a member of the basic helix-loop-helix leucine zipper (bHLH-LZ) family of transcription factors [6-8]. Expression levels of Mitf, evaluated by Western blotting and Northern blotting, vary among tissues; it is highly expressed in melanocytes, mast cells, osteoclasts, and the heart [9-11]. Thus, the roles of Mitf have been mainly examined in these cells [11-14], and Mitf activities in other tissues are largely unknown. Of the *Mitf* variants that are not the result of genetic mutation, nine *Mitf* isoforms have been identified in mice that differ in their transcriptional initiation site: *Mitf*-A, -B, -C, -D, -E, -H, -J, -M and -mc. The *Mitf* variants contain an isoform-specific first exon, while exons 2 to 9 of all *Mitf* isoforms examined to date are identical. *Mitf* isoforms are expressed in a cell type-specific manner, and their transcriptional activities are slightly but significantly different depending on the target gene [15-19]. In addition, two types of *Mitf* mRNAs with or without an 18-base insert (exon 6a) are generated by alternative use of the two acceptor sites located at the 5' end of exon 6 in *Mitf*-A, -H, -J, -M and -mc [6, 9, 20, 21]. In the

present study, we show the relatively higher expression of *Mitf-A* in the skeletal muscle, and present the potential role of *Mitf* in the progression of myogenesis.

Materials and methods

Animals and cell culture

Nine C57BL/6 mice aged 7-8 wk were used to examine the tissue distribution of *Mitf*. The experiment was approved by Azabu University Animal Experiment Committee. C2C12 myoblasts were obtained from the American Type Culture Collection (Rockville, MD). Cells were cultured in growth medium, i.e., Dulbecco's modified Eagle's medium (DMEM) with heat-inactivated 10% fetal bovine serum (FBS), 100 U/ml penicillin and 100 µg/ml streptomycin, at 37°C under a humidified 5% CO₂ atmosphere. To induce differentiation from myoblasts to myotubes, the medium was replaced at confluence (day 0) with differentiation medium consisting of DMEM with 2% horse serum supplementing the antibiotics. To isolate myotubes, cells on day 7 were trypsinized for a short time under a microscope until detachment of multinucleated cells (~2 min), followed by centrifugation to obtain a myotube-rich fraction.

RT-PCR, restriction fragment length polymorphism and quantitative RT-PCR

Total RNA isolation from tissues and cells, RT-PCR and restriction fragment length polymorphism (RFLP) were performed as described previously [21]. Quantitative RT-PCR (qRT-PCR) was carried out as described previously [22]. The used PCR primers in qRT-PCR are presented in Table 1. To compare tissue *Mitf* expression, the appropriate corrected gene was chosen using a mouse housekeeping gene primer set (TaKaRa, Otsu, Japan). The relative mRNA level was expressed as a ratio with *β-actin* to evaluate tissue distribution and *Gapdh* was used as a reference gene to examine regulatory expression in C2C12 cells.

Western blotting

To examine expression of Mitf in the skeletal muscle, thigh muscle and heart as a positive control were homogenized in RIPA buffer. After 30 min on ice, the debris was removed by centrifugation at $2,500 \times g$ for 2 min at 4°C. After centrifugation at $12,000 \times g$ for 5 min at 4°C, the supernatant was recovered and the protein concentration was measured by the bicinchoninic acid method [23]. Fifty μ g of the protein was loaded on 10% SDS-polyacrylamide gel. Western blotting was performed as described previously [24, 25]. Expression of Mitf and myosin heavy chain (Myhc) was examined by use of mouse monoclonal antibodies against Mitf (X1405M; Exalpha Biologicals) and Myhc (MY-32; Sigma), respectively. There are two types of muscle fiber, i.e., fast-twitch and slow-twitch; fast-twitch muscle fibers express Myhc2a, Myhc2b and Myhc2x, whereas slow-twitch muscle fibers do Myhc1 [26]. According to the manufacturer's manual, this antibody for Myhc recognizes fast-type muscle fibers. After incubation of the membranes with ECL Advance reagent (GE Healthcare), the chemiluminescent signals were exposed to X-ray film. Subsequently, antibodies as well as the detection reagents were stripped and reprobed with anti- α -tubulin (ab11304; Abcam) or anti- β -actin antibody (AC-15; Abcam).

Immunohistochemistry

C2C12 cells were grown on glass chamber slides coated with type I collagen (Thermo Fisher Scientific) and were fixed with 3% paraformaldehyde in PBS for 30 min, followed by treatment with 1% Triton X-100 in PBS for 10 min. After washing with PBS, cells were incubated with 3% H₂O₂ to remove endogenous peroxidase. Subsequently, cells were treated with 1.5% normal goat serum in PBS for 20 min to block nonspecific reactions. Diluted mouse monoclonal antibody against Mitf (X1405M; Exalpha Biologicals) with 0.1% bovine serum albumin in PBS at 1 : 80 was

used to identify *Mitf* expression at the protein level. After incubation with the primary antibody for 2 h at room temperature, *Mitf*-positive cells were visualized using VECTASTAIN Elite ABC kit (Vector Laboratories) and 3,3'-diaminobenzidine (DAB; Dojindo) according to the manufacturer's protocol.

siRNA transfection

To target the expression of common *Mitf*, *Mitf-A* or *Itga9* and *green fluorescent protein* (*GFP*) controls, oligonucleotides for the respective genes were synthesized by BONAC corporation (Kurume, Japan) as follows: 5'-GAAACUUGAUCGACCUCUACA-3' and 5'-UAGAGGUCGAUCAAGUUUCCA-3' for common *Mitf*, 5'-GGAGUCAUGCAGUCCGAAUTT-3' and 5'-AUUCGGACUGCAUGACUCCTT-3' for *Mitf-A*, 5'-CCUUAGUGCUCUCCGAAAGA-3' and 5'-UUUCGGAAGAGCACUAAGGUU-3' for *Itga9*, and 5'-GGUUACGUCCAGGAGCGCATT-3' and 5'-UGCGCUCCUGGACGUAGCCTT-3' for *GFP*. The siRNA for *p21* was purchased (sc-29428; Santa Cruz Biotechnology). An equal amount of the oligonucleotide was mixed for each gene to prepare siRNA. Thirty picomoles of siRNA was transfected into C2C12 cells seeded at a density of 1.5×10^4 cells in 24-well plates every 48 h. siRNA was transfected using Lipofectamine RNAiMAX (Invitrogen) according to the manufacturer's protocol. Antibiotics were not supplemented to the culture media in siRNA transfection experiments.

Morphological analysis

Cells were fixed with methanol for 2 min and subsequently stained with Giemsa staining for 20 min. Cells with more than 3 nuclei were judged as myotubes. Eight views per treatment in an experiment were analyzed. Experiments were repeated two or three times, and similar results were obtained.

BrdU incorporation

Proliferation of C2C12 cells was measured by a BrdU cell proliferation assay (Cell Proliferation ELISA, BrdU (colorimetric); Roche) according to the manufacturer's protocol.

Statistical analysis

Data are presented as the mean \pm SE. Comparisons between groups were conducted using Student's *t*-test. Results were considered significant at $P < 0.05$.

Results

Expression of *Mitf* in tissues and during myogenesis

Tissue distribution of *Mitf* was quantified by qRT-PCR. First, the expressions of 12 genes, *Atp5f1*, *B2m*, β -actin, *Gapdh*, *Hprt1*, *Pgk1*, *Ppia*, *RpLp1*, *Rps18*, *Tbp*, *Tfrc*, and *Ywhaz*, were quantified for evaluation as appropriate corrected genes; quantitative PCR using cDNA prepared from equal amounts of total RNA revealed that β -actin expression was the most stable among the tested tissues, which were evaluated by "geNorm" (<http://medgen.ugent.be/~jvdesomp/genorm/>) (data not shown). Thus, the gene transcript level of *Mitf* was corrected for that of β -actin (Fig. 1A). Expression of *Mitf* was highest in the heart, as expected. Although *Mitf* is recognized as a tissue-restricted transcription factor [6-8], its expression was detected in a wide variety of tissues. In particular, expression in the skeletal muscle was relatively higher. Previous studies indicated *Mitf* expression in the skeletal muscle [9, 27], but the role of *Mitf* is not known. Thus, we characterized the expression and function of *Mitf* in the skeletal muscle and during myogenesis in detail. Examining *Mitf* isoforms differing in transcriptional initiation site in the skeletal muscle indicated that more than 99% of *Mitf*

was *Mitf-A*, and that *Mitf-H* and *-J* were also expressed significantly (Fig. 1B).

In a C2C12 myotube differentiation model, C2C12 myoblasts fuse to form multinucleated myotube cells upon serum starvation on day 0 [28]. To evaluate gene expression in C2C12 cells, we chose *Gapdh* instead of β -actin as a reference gene; qPCR using cDNA prepared from equal amount of total RNA indicated gradual decrease in β -actin expression with progression of myogenesis, whereas expression of *Gapdh* was relatively constant (Supplementary Fig. 1). Total *Mitf* expression level increased up to day 8 and then reached a plateau (Fig. 1C). Similar to the expression pattern in the skeletal muscle, *Mitf-A* was the main isoform (59-76% of total *Mitf*). In addition, *Mitf-J* but not *-H* was expressed. The expression pattern of *Mitf* isoform was constant during myogenesis; the ratio of *Mitf-A* to *Mitf-J* was 1.5 to 3.2 : 1. Expression of *Mitf* in the skeletal muscle and C2C12 cells was also verified at the protein level by Western blot analyses (Fig. 1D). In addition, consistent with the changes at the mRNA level, expression of *Mitf* protein was increased after differentiation stimulation (Fig. 1E). Furthermore, *Mitf* was exclusively localized in the nucleus of C2C12 cells (Fig. 1F). We also examined the ratio of gene transcripts of *Mitf* with exon 6a to that of *Mitf* without exon 6a by PCR-RFLP analyses; the ratios of *Mitf-A* and *Mitf-J* were relatively constant during myogenesis (Fig. 1G).

Disruption of *Mitf* expression inhibits myotube formation by blocking increased expression of p21 and *Itga9* induction

To clarify the roles of *Mitf* in myogenesis, we evaluated effects of decreased expression of *Mitf*, which was achieved by transfection with siRNA for *Mitf* (Supplementary Fig. 2A, lanes 2 and 3, and B). Transfection of siRNA for common *Mitf* effectively decreased the emergence of multinucleated myotubes on day 6, as compared with *GFP* (Fig. 2A). Knockdown of *Mitf-A* also blocked the formation of thick myotubes (Fig. 2B,

Supplementary Fig. 2C). Morphological analyses on day 6 indicated that the number of multinucleated cells, which were defined as cells with more than 3 nuclei, was significantly decreased by transfection of siRNA for *Mitf* (Fig. 2C). We also evaluated the differentiated myotubes in detail; knockdown of *Mitf* increased the proportion of myotubes with 3 to 5 nuclei, but decreased that of myotubes with more than 6 nuclei (Fig. 2D). Similar results were also obtained in C2C12 cells transfected with siRNA for *Mitf-A* (Supplementary Fig. 3). Furthermore, *Mitf* knockdown decreased the expression of Myhc, a myotube-specific protein [3-5], in C2C12 cells on day 8 (Fig. 2E, lanes 1 and 2). These results suggest that *Mitf* is required not only for myoblast-myoblast fusion but also for maturation of nascent myotubes. We also examined effects of forced *Mitf* expression on myotube formation; the expression did not enhance myogenesis (data not shown).

Molecular bases of decreased myotube formation by *Mitf* knockdown were then explored. Myogenesis is regulated through modulation of the expression and activity of MRFs [29, 30]; however, gene transcript levels of *Myf5*, *Myod*, *Myogenin* and *Mrf4* were unchanged by *Mitf* knockdown, suggesting that impairment of myogenesis resulting from *Mitf* knockdown is not due to altered expression of MRFs (Fig. 3A-D).

Other than MRFs, several molecules related to cell attachment and fusion, such as *Adam12*, *Calpastatin*, *Caveolin3*, *Cdh15*, *Ctsb*, *Itga3*, *Itga4*, *Itga6*, *Itga9*, *Itgb1*, *Myof*, and *v-Cam1* are known to regulate myotube differentiation [2, 31-34]. In addition, the cDNA microarray database (<http://www.ncbi.nlm.nih.gov/geo/>) indicated that the expressions of *Ccna2*, *Itga5*, *p21*, *p57*, *Ptger4*, *Rb1*, and *Vcl* increased with differentiation. In view of *Mitf* as a transcription factor, we expected that *Mitf* is involved in myogenesis through transcriptional activation of these myogenesis-regulating genes. Thus, the effects of decrease in *Mitf* expression on the

expression level of these genes were explored. We found that gene transcript levels of *p21* and *Itga9* after differentiation stimulation were decreased by transfection of siRNA for common *Mitf*; expression of *p21* was increased in response to differentiation stimulation, and *Mitf* knockdown blocked the increased expression of *p21* (Fig. 3E). Significant expression of *Itga9* was detected after day 4, and the expression level was decreased by transfection of siRNA for *Mitf* (Fig. 3F). Decreased expression of *p21* and *Itga9* was also detected in *Mitf-A*-knockdown cells (Supplementary Fig. 4). Gene transcript levels of the other genes were unaffected by *Mitf* knockdown (Supplementary Fig. 5).

In a C2C12 myogenesis cell model, not all myoblasts fuse into myotubes; co-existence of proliferating myoblasts and myotubes is detected after differentiation stimulation [35-37]. We separated the myotube-rich fraction by limited trypsinization to explore cells affected by *Mitf* knockdown. Although *Myhc2a* expression was not significantly different between the myotube fraction and the residual cell fraction in control cells (Fig. 4A), *Myhc2b* and *Myhc2x* were predominantly expressed in the myotube fraction as expected (Fig. 4B and C). Expression of *Myhc2x* in the myotube fraction was significantly lower in *Mitf*-knockdown cells than in control cells, whereas that of *Myhc2a* in the myotube fraction was higher in the *Mitf*-knockdown cells. The *Myhc2b* expression in the myotube fraction was comparable between control cells and in *Mitf*-knockdown cells. Considering that *Myhc2x* was the major isoform of type 2 *Myhc* (> 93%) (Fig. 4D), total expression of *Myhc* constituting of fast-twitch myofibers was largely limited to the myotube fraction, and was decreased by *Mitf* knockdown; the latter was consistent with the results on *Myhc* expression at the protein level (Fig. 2E).

The extent of the decreased expression of *Mitf* resulting from knockdown of *Mitf* was comparable between the myotube fraction and the residual cell fraction, indicating

effective inhibition of *Mitf* expression in both myoblasts and myotubes (Fig. 5A). Expression of *p21* was significantly higher in the myotube fraction than in the residual cell fraction (Fig. 5B). Knockdown of *Mitf* equally decreased the expression of between the two fractions. Expression of *Itga9* was also significantly higher in the myotube fraction (Fig. 5C). Similar to the expression of *p21*, *Mitf* knockdown down-regulated the expression of *Itga9* in both fractions.

Cell cycle exit in response to differentiation stimulation is a prerequisite for myotube formation [2]; p21, a cyclin-dependent kinase inhibitor inducing cell cycle exit, plays a role in post-mitotic myogenesis, although it also maintains anti-apoptotic states in differentiated myocytes [1]. To link the decreased *Mitf*-induced inhibition of myotube formation and blockage of *p21* induction, effects of the decreased *Mitf* expression on BrdU uptake were next examined; BrdU uptake was significantly increased by transfection of siRNA for *Mitf* on day 4-6 (Fig. 5A). Knockdown of *p21*, however, did not affect BrdU uptake (Fig. 5B). Similar to *Mitf* knockdown, decreased expression of p21 inhibited emergence of matured and thick myotubes (Fig. 5C). In addition, it significantly decreased the number of multinucleated cells (Fig. 5D), and increased and decreased the proportion of myotubes with 3 to 5 nuclei and those with more than 6 nuclei, respectively (Fig. 5E).

We next explored the effects of *Itga9* knockdown on myotube formation. The morphology of cells transfected with siRNA for *Itga9* indicated that, compared to control cells, thinner myotubes were evident by *Itga9* knockdown, suggesting that *Itga9* is required for myotube maturation (Fig. 6A), which was verified by morphometry. The multinucleated cell number itself was not affected by knockdown of *Itga9* (Fig. 6B), but the proportion of the number of myotubes with 3-5 nuclei in a cell to that of total myotubes was significantly increased, and that with more than 6 nuclei was decreased

(Fig. 6C). Consistent with the results, knockdown of *Itga9* gene resulted in the decreased expression of Myhc (Fig. 2E, lanes 1 and 3).

Discussion

Here, we demonstrate that 1) A isoform of *Mitf* mRNA is abundant in the skeletal muscle, 2) *Mitf-A* expression increased with progression of myogenesis, 3) knockdown of *Mitf* mRNA disrupts myotube formation through inhibition of myoblast-myoblast fusion and subsequent myoblast-myotube fusion, but does not affect the expression of MRFs, and 4) expression of *p21*, a cyclin-dependent kinase inhibitor, and *Itga9* is regulated by *Mitf* in a stage-dependent manner for appropriate myogenesis. The present results indicate a novel role of a tissue-restricted transcription factor *Mitf* in the regulation of myogenesis, which is probably mediated by an MRF-independent pathway.

Mitf regulates myogenesis in multiple steps. Expression of *p21* and *Itga9* was modulated by decreased expression of *Mitf*; down-regulation of *p21* expression resulting from knockdown of *Mitf* mRNA was limited to post-differentiation, and significant *Itga9* expression was detected just after differentiation stimulation. Considering that significant expression of *Mitf* was detected prior to differentiation stimulation, the gene expression of *p21* and *Itga9* could not be regulated by *Mitf* alone, but in concert with *Mitf* and as yet unidentified factor(s). Transfection of siRNA for *Mitf* resulted in down-regulated expression of *Mitf* both in myoblasts and myotubes. Thus, the precise mechanism of how *Mitf* regulates not only *p21* in myoblasts and myotubes but also *Itga9* expression in myotubes remains unclear. Since *Mitf* binds to the E-box (CANnTG) located in the 5'-untranslated region and activates transcription [6-8], *Mitf* may directly regulate transcription of *p21* and *Itga9*. Alternatively, it is possible that a factor

regulated by *Mitf* in myoblasts acts as a regulator to induce *p21* or *Itga9* in myotubes.

A target gene of *Mitf* was *Itga9*. Among members of the integrin family, *Itga3*, 4, 6 and 9 have been suggested to regulate myogenesis [2, 31, 33, 34]. Transcription of *Itga4* was activated through *Mitf* binding to the E-box located in the 5'-untranslated region in mast cells [38]. In the present study, however, *Itga4* mRNA was not decreased but rather increased by transfection of siRNA for *Mitf* in C2C12 cells (Supplementary Fig. 2H), suggesting that transcription by *Mitf* is regulated in a cell context-dependent manner. In addition, *Mitf* knockdown did not affect the expression level of *Itga3* and 6 (Supplementary Fig. 2G and J). In a study using a human mononucleated myogenic precursor cell culture system, addition of anti-INTEGRIN $\alpha 9\beta 1$ antibody to the culture medium decreased the proportion of nuclei included in large myotubes (≥ 5 nuclei), whereas the proportion of nuclei incorporated in small myotubes (2-4 nuclei) was unchanged [33]. In the present study using a murine myogenesis model, transfection with siRNA for *Itga9* decreased the proportion of large myotubes (≥ 6 nuclei) and increased that of small myotubes (3-5 nuclei), but did not affect the number of multinucleated cells. Taking these results together, *Itga9* is suggested to promote the growth of preformed myotubes rather than the formation of nascent myotubes during myogenesis.

Effects of knockdown of *Mitf* mRNA partly overlapped but were distinct from those of *Itga9* knockdown; the number of multinucleated cells was decreased by *Mitf* knockdown. This suggests that *Mitf* is involved in both myoblast-myoblast fusion and subsequent maturation of nascent myotubes. It is possible that *Mitf* regulates myoblast-myoblast fusion through the increase in *p21* expression; regulatory expression of *p21* by *Mitf* has also been shown in melanocytes [39]. Cell cycle inhibition and apoptosis of myoblasts precede to myoblast-myoblast fusion, and both processes are

necessary for the cell fusion [1]. p21 is principally involved as a molecule to establish post-mitotic and apoptosis-resistant states [1]; BrdU uptake was not detected in p21-positive myoblasts [40], and forced expression of p21 but not inactive p21 inhibited apoptosis of C2C12 myoblasts [41]. In fact, *p21* knockdown decreased the myotube number and increased proportion of small myotubes, suggesting that p21 expression is required for efficient myoblast-myoblast fusion.

Knockdown of *p21* did not increase BrdU uptake on day 4 and 6; it may be offset effects of the cell growth inhibition and the anti-apoptotic activity. In view of significant inhibition of BrdU uptake in *Mitf*-knockdown cells on day 4 and 6, *Mitf* regulates expression and activity of additional molecule(s) unidentified in this study.

Bharti et al. [19] revealed that *Mitf-A* and *-J* are expressed throughout eye development in both retina and pigment epithelium, whereas expression of *Mitf-D* and *-M* was limited to pigment epithelium. In addition, *Mitf-H* was preferentially found in pigment epithelium with temporal expression profile. Unlike the eye development, the proportion of expressed *Mitf* isoforms, i.e., *Mitf-A* and *Mitf-J* was almost constant during myogenesis of C2C12 cells, although total *Mitf* expression was increased with progression of myogenesis (Fig. 1C). Thus, expression of *Mitf* isoforms is tissue-specific and stage-dependent. In view of different activity as transcription factors between the isoforms [15-18], regulation on the use of alternative promoter must be clarified in future studies.

Mitf encoded by the mutant *mi* allele deletes one of four consecutive arginines in the basic domain, and acts as a dominant-negative mutant [9, 27, 42]. The *mi/mi* mutant mice exhibited the pleiotropic effects of microphthalmia, depletion of pigment in both hair and eyes, and osteopetrosis resulting from defects of osteoclastogenesis [9, 14]. In

addition to these phenotype alterations, Katayama et al. [43] recently showed that masseter muscle development was disrupted in *mi/mi* mutant mice; they speculated that the disorder is a secondary event related to abnormal tooth formation related to osteoclast dysfunction; however, in view of the present results showing direct inhibition of myogenesis by decreased expression of *Mitf*, muscle development itself may be disturbed in *mi/mi* mice.

The present study indicates significant expression of *Mitf* in the skeletal muscle from re-evaluation of tissue distribution of *Mitf* by sensitive qRT-PCR analyses. Evaluation of *Mitf* activity clarifies its role as a positive regulator during myogenesis. Because *Mitf* is expressed also in other tissues with a variation of expression level, future studies should be directed to elucidate the role of *Mitf* in as yet uncharacterized tissues.

Figure legends

Fig. 1. *Mitf* expression is highly expressed in the skeletal muscle and increases with progression of myogenesis in C2C12 cells

(A) *Mitf* expression in various tissues was measured by qRT-PCR. *Mitf* expression was expressed as a ratio to β -actin expression. Data are shown as the mean \pm SE. (B) Expression of *Mitf* isoform differing with transcriptional initiation site in the skeletal muscle was identified by qRT-PCR using isoform-specific 5'-primer and 3'-primer spanning the common *Mitf*. The percentage of the expression of each *Mitf* isoform to that of total *Mitf* was calculated. Data are shown as the mean \pm SE. (C) C2C12 myoblasts were cultured to confluence (day 0) in growth medium, followed by culture in differentiation medium. Time-course changes in expression of *Mitf* isoform differing with transcriptional initiation site during myogenesis were examined in C2C12 cells. *Mitf* expression was expressed as a ratio to *Gapdh* expression. Data are shown as the mean \pm SE (n = 2). (D) Expression of *Mitf* in the skeletal muscle. Protein extracted from heart, thigh muscle and C2C12 cells was subjected to Western blot analyses to examine *Mitf* expression at the protein level. A representative result of Western blot is shown. In the heart, *Mitf*-H as well as *Mitf*-A is mainly expressed shown in (B). Note that calculated molecular weight of *Mitf*-H and *Mitf*-A is 56.8 k and 58.6 k, respectively. (E) Time-course changes in expression of *Mitf* protein were examined during myogenesis of C2C12 cells. A representative result of Western blot is shown. (F) Immunolocalization of *Mitf* in C2C12 cells. C2C12 myoblasts were fixed and reacted with (*right*) or without (*left*) mouse monoclonal anti-*Mitf* antibody. Subsequently, cells were reacted with anti-mouse IgG antibody, and the antibody was visualized. A representative cell staining is shown. (G) The ratio of exon 6a-containing *Mitf* isoforms (exon 6a + 6b) to non-exon 6a-containing isoforms (exon 6b) was evaluated in C2C12 cells. PCR products of *Mitf* -A and -J were digested by *Hinf*I, and DNA fragments with or without exon 6a were separated by PAGE. A photograph of a representative gel

stained with ethidium bromide is shown.

Fig. 2. *Mitf* expression is required for efficient myotube formation

C2C12 cells were transfected with siRNA for *GFP* as a control, common *Mitf* or *Mitf-A* every 2 days after day -2. (A) Effect of *Mitf* knockdown on myogenesis was evaluated. Representative phase-contrast images on day 0, 2, 4, and 6 are presented. (B) Role of *Mitf-A* was examined. Representative cells stained by Giemsa solution on day 6 are presented. (C and D) Myotube formation was evaluated in *Mitf*-knockdown C2C12 cells. Cells were transfected with siRNA for *GFP* as a control or *Mitf*, and morphology was evaluated on day 6. After staining with Giemsa solution, cell number and the number of nuclei were calculated. (C) Ratio of multinucleated cell number to total cell number was calculated, and the ratio of cells transfected with siRNA for *GFP* was set to 1. (D) Number of cells with 3 to 5, 6 to 10 or >11 nuclei were counted, and percentage to total multinucleated cells is shown. Data are shown as the mean \pm SE (n = 6). * and **: $P < 0.05$ and $P < 0.01$, respectively, as compared to control. (E) Expression of *Myhc* in response to transfection of siRNA for *GFP* as a control, *Mitf* or *Itga9* in C2C12 cells on day 8 was examined by Western blot analyses. Subsequently, the membranes were reprobed with anti- β -actin antibody.

Fig. 3. *p21* and *Itga9* are targets of *Mitf* for progression of myogenesis

C2C12 cells were transfected with siRNA for *GFP* as a control or common *Mitf* every 2 days after day -2. Gene expression of *Myf5* (A), *Myod* (B), *Myogenin* (C), *Mrf4* (D), *p21* (E) and *Itga9* (F) was quantified by qRT-PCR. The expression was normalized to *Gapdh* expression. The expression in cells on day -2 was set to 1 for *Myf5*, *Myod*, *Myogenin*, *Mrf4* and *p21*, and that in cells transfected with siRNA for *GFP* on day 4 was set to 1 for *Itga9*. Data are shown as the mean \pm SE (n = 2).

Fig. 4. Knockdown of *Mitf* in myoblasts and myotubes down-regulates expression of *Myhc2x*

C2C12 cells were transfected with siRNA for *GFP* as a control or common *Mitf* every 2 days after day -2. On day 7, multinucleated myotubes were separated from the residual cells by limited trypsinization. Expression of *Myhc2a* (A), *Myhc2b* (B) and *Myhc2x* (C) was quantified by qRT-PCR, and normalized to *Gapdh* expression. The expression in residual cells after limited trypsinization in the control group was set to 1. (D) The percentage of the expression of each *Myhc* isoform to that of total type II *Myhc* was calculated. Data are shown as the mean \pm SE ($n = 3$). a, b, c, d: Means that do not have a common letter on the bar differ significantly ($P < 0.05$).

Fig. 5. Knockdown of *Mitf* in myoblasts and myotubes down-regulates expression of *p21* and *Itga9*

C2C12 cells were transfected with siRNA for *GFP* as a control or common *Mitf* every 2 days after day -2. On day 7, multinucleated myotubes were separated from the residual cells by limited trypsinization. Expression of *Mitf* (A), *p21* (B), and *Itga9* (C) was quantified by qRT-PCR, and normalized to *Gapdh* expression. The expression in residual cells after limited trypsinization in the control group was set to 1. Data are shown as the mean \pm SE ($n = 3$). a, b, c, d: Means that do not have a common letter on the bar differ significantly ($P < 0.05$).

Fig. 6. *p21* is involved in *Mitf*-mediated myogenesis

(A and B) Role of *Mitf* and *p21* in BrdU uptake in C2C12 cells was evaluated. (A) Cells were transfected with siRNA for *GFP* as a control or common *Mitf* every 2 days after day -2, and BrdU uptake was examined on day -1, 0, 4 and 6. BrdU uptake in control cells on day -1 was set to 100. (B) Cells were transfected with siRNA for *GFP* or *p21* every 2 days after day 2, and BrdU uptake was examined on day 4 and 6. Data are

shown as the mean \pm SE (n = 3-4). **: $P < 0.01$, as compared to control. (C-E) Role of p21 in myogenesis was evaluated. Cells were transfected with siRNA for *GFP* or *p21* every 2 days after day 2. (C) Representative cells stained by Giemsa solution on day 6 are shown. (D and E) Myotube formation was evaluated in *p21*-knockdown C2C12 cells. After staining cells with Giemsa solution on day 6, cell number and the number of nuclei were calculated. (D) Ratio of multinucleated cell number to total cell number was calculated, and the ratio of cells transfected with siRNA for *GFP* was set to 1. (E) Number of cells with 3 to 5, 6 to 10 or >11 nuclei was counted, and percentage to total multinucleated cells is shown. Data are shown as the mean \pm SE (n = 4). * and **: $P < 0.05$ and $P < 0.01$, respectively, as compared to control.

Fig. 7. *Itga9* are involved in *Mitf*-mediated myogenesis

(A-C) Role of *Itga9* in myogenesis was evaluated. Cells were transfected with siRNA for *GFP* or *Itga9* every 2 days after day -2. (A) Representative cells stained by Giemsa solution on day 6 are shown. (B and C) Myotube formation was evaluated in *Itga9*-knockdown C2C12 cells. After staining cells with Giemsa solution on day 6, cell number and the number of nuclei were calculated. (B) Ratio of multinucleated cell number to total cell number was calculated, and the ratio of cells transfected with siRNA for *GFP* was set to 1. (C) Number of cells with 3 to 5, 6 to 10 or >11 nuclei was counted, and percentage to total multinucleated cells is shown. Data are shown as the mean \pm SE (n = 4). **: $P < 0.01$, as compared to control.

Supplementary Fig. 1 Time-course changes in expression of *Gapdh* and β -actin during myogenesis of C2C12 cells

C2C12 myoblasts were cultured to reach confluence (day 0) in growth medium, followed by culture in differentiation medium. Expression of *Gapdh* and β -actin using

cDNA prepared from 5 ng of total RNA was quantified by qRT-PCR, and normalized to *Hprt1* expression. The expression on day 0 was set to 1. Data are shown as the mean \pm SE (n = 2).

Supplementary Fig. 2 Effects of Mitf knockdown on Mitf expression in C2C12 cells

(A) C2C12 cells were transfected with siRNA for *GFP* as a control (c, lane 2) or common *Mitf* (M, lane 3) for 2 days. Western blot analyses were performed to examine Mitf expression. As a positive control, lysates of B16 melanoma cells were used (lane 1). B16 cells express mainly Mitf-M, whereas C2C12 cells predominantly express Mitf-A as shown in Fig. 1C. Note that calculated molecular weight of Mitf-M (46.8 k) is smaller than that of Mitf-A (58.6 k). (B and C) C2C12 cells were transfected with siRNA for *GFP* as a control, common *Mitf* or *Mitf-A* every 2 days after day -2. Gene expression of common *Mitf* (B) and *Mitf-A* (C) was quantified by qRT-PCR. The expression was normalized to *Gapdh* expression. The expression in cells on day -2 was set to 1. Data are shown as the mean \pm SE (n = 2).

Supplementary Fig. 3 Impaired myotube formation in C2C12 cells transfected with siRNA for Mitf-A

C2C12 cells were transfected with siRNA for *GFP* as a control or *Mitf-A* every 2 days after day -2. (A and B) Myotube formation was evaluated in *Mitf-A*-knockdown C2C12 cells. Cells were transfected with siRNA for *GFP* as a control or *Mitf-A*, and morphology was evaluated on day 6. After staining with Giemsa solution, cell number and the number of nuclei were calculated. (A) Ratio of multinucleated cell number to total cell number was calculated, and the ratio of cells transfected with siRNA for *GFP* was set to 1. (B) Number of cells with 3 to 5, 6 to 10 or >11 nuclei were counted, and percentage to total multinucleated cells is shown. Data are shown as the mean \pm SE (n =

6). * and **: $P < 0.05$ and $P < 0.01$, respectively, as compared to control.

Supplementary Fig. 4 Decreased expression of p21 and Itga9 in C2C12 cells transfected with siRNA for Mitf-A

C2C12 cells were transfected with siRNA for *GFP* as a control or *Mitf-A* every 2 days after day -2. Gene expression of *p21* (A) and *Itga9* (B) was quantified by qRT-PCR. The expression was normalized to *Gapdh* expression. The expression in cells transfected with siRNA for *GFP* on day -2 was set to 1. Data are shown as the mean \pm SE (n = 2).

Supplementary Fig. 5 Effects of Mitf knockdown on gene expression in C2C12 cells

C2C12 cells were transfected with siRNA for *GFP* as a control or common *Mitf* every 2 days after day -2. Gene expression of *Adam12* (A), *Calpastatin* (B), *Caveolin3* (C), *Ccna2* (D), *Cdh15* (E), *Ctsb* (F), *Itga3* (G), *Itga4* (H), *Itga5* (I), *Itga6* (J), *Itgb1* (K), *Myof* (L), *p57* (M), *Ptger4* (N), *Rb1* (O), *v-Cam1* (P), and *Vcl* (Q) was quantified by qRT-PCR. The expression was normalized to *Gapdh* expression. The expression in cells on day -2 was set to 1. Data are shown as the mean \pm SE (n = 2).
