Organic reactions mediated by electrochemically generated ArS$^+$

Kouichi Matsumoto, Seiji Suga and Jun-ichi Yoshida

Low-temperature electrochemical oxidation of ArSSAr was carried out to generate a pool of ArS$^+$. Spectroscopic studies (1H NMR and CSI-MS) of the resulting solution revealed the accumulation of ArS(ArSSAr)$^+$. The resulting ArS$^+$ pool reacted with alkenes and alkynes to give diarylthio-substituted products. ArS$^+$ pool rapidly reacted with thioacetals to give the corresponding alkoxy carbienium ion pools, which reacted with various carbon nucleophiles (indirect cation pool method). The reaction of the alkoxy carbienium ion pools with stilbene derivatives in the presence of ArSSAr gave thiocroman derivatives. In addition to such stoichiometric reactions, a catalytic amount of ArS$^+$ serves as an initiator and a chain carrier of some cationic chain reactions involving intramolecular carbon-carbon bond formation. In-situ generation of ArS$^+$ by electrochemical oxidation of ArSSAr with a catalytic amount of electricity in the presence of a substrate is also effective for such cationic chain reactions.

1 Introduction

Organic electrochemistry provides a straightforward, efficient, and tunable method for making and modifying organic molecules under mild conditions. The advantages of this method lie in its ability to oxidize or reduce organic compounds of a wide range of oxidation and reduction potentials selectively generating highly reactive intermediates that are useful in organic synthesis. It is also noteworthy that electrochemical processes are applicable to organic compounds bearing a variety of functional groups, because they usually proceed without using strong acids or bases. Based on such features, many synthetic transformations that are unique to electrochemistry have been developed so far. Thus, the electrochemical method opens new possibilities of synthesizing.

Kouichi Matsumoto was born in 1982 in Nara, Japan. He received his Ph.D. from Kyoto University in 2010 under the supervision of Prof. Juntichi Yoshida. In 2010 he joined the group of Prof. Shigenori Kashimura at Kinki University as an Assistant Professor. His current research interests include electro-organic chemistry.

Seiji Suga was born in 1963 in Hiroshima. He received his Ph.D. from Nagoya University under the supervision of Prof. Ryoji Noyori. He became a postdoctoral fellow (JSPS Postdoctoral Fellowships for Research Abroad) with Prof. Jack E. Baldwin at Oxford University. In 1996 he joined the group of Prof. Jun-ichi Yoshida at Kyoto University as Instructor, and was promoted to Lecturer (1999) and Associate Professor (2004). In 2008 he was appointed as Professor at Okayama University. His current research interests include electron-transfer reactions and synthetic processes of organic compounds.

2 Generation of \textit{`ArS'\textsuperscript{+}} by low-temperature electrochemical oxidation of ArSSAr and its characterization by spectroscopic studies

\textit{`ArS'\textsuperscript{+}} is considered to be a highly electrophilic reagent,\textsuperscript{9} although some doubts have been advanced of its existence in this form in the solution phase. Extensive studies on the chemical methods for generating \textit{`ArS'\textsuperscript{+}} have been reported in the literature, which include chemical oxidation of ArSSAr\textsuperscript{10} and the reactions of ArS-X with Lewis acids.\textsuperscript{11} The electrochemical oxidation of ArSSAr serves as a useful method for generating \textit{`ArS'\textsuperscript{+}} (Scheme 2). The radical cation of ArSSAr produced by one electron oxidation of ArSSAr undergoes the cleavage of the sulfur-sulfur bond to give ArS\textsuperscript{+} and ArS\textsuperscript{-}. ArS\textsuperscript{-} is further oxidized to give ArS\textsuperscript{+}. Thus, the electrochemical generation, in principle, does not produce any by-products, and therefore is superior to the chemical generation, which uses toxic oxidizing reagents and produces byproducts derived from them.

![Scheme 2. Electrochemical oxidation of ArSSAr.](image2)

\textbf{Jun-ichi Yoshida} was born in Osaka, Japan in 1952. He graduated from Kyoto University in 1975, where he received his doctor’s degree under the supervision of Prof. Makoto Kumada in 1981. In 1979 Yoshida joined the faculty at Kyoto Institute of Technology as an Assistant Professor. In the meantime, he visited University of Wisconsin during 1982-1983, where he joined the research group of Prof. B. M. Trost. In 1985 he moved to Osaka City University, where he was promoted to an Associate Professor in 1992. In 1994 he was appointed as a full Professor of Kyoto University. Awards: the Progress Award of Synthetic Organic Chemistry, Japan (1987), the Chemical Society of Japan Award for Creative Work (2001), Nagoya Silver Medal (2006), Humboldt Research Award (2007), Green and Sustainable Chemistry Award (2010), and Dogane Award (2010). His research interests include integrated organic synthesis on the basis of reactive intermediates, organic electron transfer reactions, organometallic reactions, and microreactors.

\textbf{Fig. 1} An electrochemical apparatus consisting of an H-type divided cell and DC power supply for generation of \textit{`ArS'\textsuperscript{+}} by the oxidation of ArSSAr at \textdegree C.

\textsuperscript{1}H NMR (80 \textdegree C) spectrum of the anodic solution obtained by the electrochemical oxidation of ArSSAr (Ar = p-FC\textsubscript{6}H\textsubscript{4}) in Bu\textsubscript{4}NBF\textsubscript{4}/CD\textsubscript{3}Cl\textsubscript{2}–CH\textsubscript{2}Cl\textsubscript{2} at \textdegree C (0.67 F/mol) showed a spectrum similar to that of ArS(ArSSAr)\textsuperscript{+} generated by the reaction of ArSSAr and SbCl\textsubscript{6} (15\textsubscript{10b}, 10\textsubscript{c}). CSI-MS (cold-spray ionization mass spectroscopy)\textsuperscript{13} (spray temperature: 0 \textdegree C) provided strong evidence for the formation of ArS(ArSSAr)\textsuperscript{+} (m/z = 381) (Fig. 2). Therefore, it was concluded that ArS(ArSSAr)\textsuperscript{+} was the species that was generated and accumulated by the low temperature electrolysis of ArSSAr in Bu\textsubscript{4}NBF\textsubscript{4}/CH\textsubscript{3}Cl\textsubscript{2}.\textsuperscript{16} In fact, 0.67 F/mol is the theoretical amount of electricity to convert ArSSAr to ArS(ArSSAr)\textsuperscript{+}. 

\textsuperscript{15} ArS(ArSSAr)\textsuperscript{+} is suggested as an intermediate. Thus, there are several arguments on the chemistry of ArS\textsuperscript{+}. Therefore, the characterization of electrochemically generated ArS\textsuperscript{+} has received significant research interest.

The electrochemical oxidation of ArSSAr (oxidation potential: 1.47 V (Ar = p-FC\textsubscript{6}H\textsubscript{4})) is usually carried out in an H-type cell equipped with a carbon felt anode and a platinum plate cathode (Fig. 1). In the anodic chamber is placed a solution of ArSSAr (0.4 mmol) in 0.3 M Bu\textsubscript{4}NBF\textsubscript{4}/CH\textsubscript{3}Cl\textsubscript{2} (8 mL). In the cathodic chamber are placed 0.3 M Bu\textsubscript{4}NBF\textsubscript{4}/CH\textsubscript{3}Cl\textsubscript{2} (8 mL) and trifluoromethanesulfonic acid (TIOH) (0.27 mmol) to facilitate the reduction of protons in the cathodic process. The constant current electrolysis (8 mA) is carried out at \textdegree C with magnetic stirring.

3 Stoichiometric reactions

3.1 Reactions with alkenes and alkynes

The electrochemically generated ArS(ArSSAr)+BF₄⁻ rapidly reacts with an alkene even at low temperatures. For example, the reaction of ArS(ArSSAr)+BF₄⁻ with 1-methylcyclohexene at –78 °C followed by quenching with MeOH as a nucleophile afforded adduct 1 (Markovnikov product) in 68% yield (Scheme 3). Presumably, the reaction proceeded by initial formation of an episulfonium ion intermediate. A MeO group was introduced on the tertiary carbon, suggesting that MeOH attacked a partially developed carbocationic center. It is also noteworthy that the anti addition product was obtained exclusively. These observations are quite similar to those obtained for ArS⁺ generated by other methods in the absence of ArSSAr. The use of H₂O as a quenching nucleophile led to the formation of 2 in a similar manner (Scheme 3).

![Scheme 3](image)

Scheme 3. The reactions of ArS(ArSSAr)+BF₄⁻ (Ar = p-FC₆H₄) with 1-methylcyclohexene followed by addition of a quenching nucleophile.

However, the use of ketene silyl acetal 3 as a quenching nucleophile led to anti addition of two ArS groups to give compound 5. No appreciable carbon–carbon bond formation took place. The formation of 5 indicated that ArSSAr attacked the episulfonium ion as a nucleophile. Use of an allylsilane, such as 4 as a quenching nucleophile also gave rise to the formation of 5. Et₃N was also found to be an effective quenching nucleophile (Scheme 4). Diarylthio-substituted compounds were obtained in good yields (6-9). The stereoselectivity of the reactions was high, and anti addition products were obtained. Although several methods for this type of transformation have been reported in the literature, the present method serves as an alternative convenient way to access such compounds.

![Scheme 4](image)

Scheme 4. The reactions of ArS(ArSSAr)+BF₄⁻ (Ar = p-FC₆H₄) with alkenes at –78 °C using Et₃N as a quenching nucleophile.

Although the reaction mechanism has not yet been fully clarified, the following mechanistic arguments seem to be reasonable (Scheme 5). In the first step, episulfonium ion intermediate 10 is generated by the reaction of ArS(ArSSAr)+BF₄⁻ with an alkene. Nucleophilic attack of ArSSAr on 10 opens the three-membered ring to give sulfonium ion intermediate 11. There is an equilibrium between 10 and 11. A hard quenching nucleophile such as MeOH or H₂O selectively attacks 10 to give the corresponding product 12 (pathway I). On the other hand, a soft quenching nucleophile such as ketene silyl acetal 3, allylsilane 4, and Et₃N selectively attacks 11 to cleave the S-S bond giving diarylthio-substituted compound 13 as the final product (pathway II).

![Scheme 5](image)

Scheme 5. Plausible reaction mechanism (Nu = nucleophile).

It is interesting that the reactions of ArS(ArSSAr)+BF₄⁻ with alkenes at higher temperatures give thiofluorinated product exclusively. For example, thiofluorinated compound 14 was obtained exclusively in the reaction with 1-octene at 0 °C, whereas the reaction at –78 °C gave diarylthio-substituted compound 7 as shown in Scheme 6. In this case, a fluoride ion, which is derived from the anionic part of supporting electrolyte (BF₄⁻), attacked the episulfonium ion intermediate 10 as a nucleophile before a quenching reagent was added to the reaction mixture (Scheme 5).
transferred to another location to be used in the subsequent reaction with a nucleophile before it decomposes, has been developed. However, there is another way to solve the problem, which is based on the ex-cell indirect electrochemical method. In this method, a highly reactive reagent is once generated and accumulated electrochemically and is subsequently allowed to react with a precursor to generate an organic cation rapidly. Because the process of generating an organic cation takes place in a homogeneous solution, it could be completed in a short period. Therefore, the decomposition of unstable organic cations might be avoided. For example, the combination of thiaacetals, as precursors and ArS(ArSSAr)$^+$ as a cation-generating reagent seems to be suitable for rapid generation of alkoxy carbocations, because ArS(ArSSAr)$^+$ is considered to be highly thiophilic.

Thus, ArS(ArSSAr)$^+$ is generated by the electrochemical oxidation of ArSSAr (Ar = p-FC$_6$H$_4$) in Bu$_4$NF/CH$_2$Cl$_2$ at −78 °C (step 1) (Scheme 8). The resulting solution is reacted with a thiaacetal 20 to generate the corresponding alkoxy carbocation ion 21 (step 2). This process requires only 5 min at −78 °C. In the third step, allyltrimethylsilane (2 equiv) is added to obtain the final product 22 in 90% yield (step 3).

Scheme 8. Indirect cation pool method to generate and accumulate an alkoxy carbocation (Ar = p-FC$_6$H$_4$).

The formation of 21 was confirmed by NMR spectroscopy at −80 °C (Scheme 8). A solution obtained by the reaction of 20 with the electrochemically generated ArS(ArSSAr)$^+$BF$_4^-$ (Ar = p-FC$_6$H$_4$) exhibited signals at 9.53 and 4.92 ppm due to the methine proton and methyl protons, respectively (H NMR), and a signal at 230.6 ppm due to the methine carbon ($^{13}$C NMR). These chemical shifts were quite similar to those obtained by the direct electrochemical oxidation of C$_8$H$_7$CH(OMe)SiMe$_3$ (9.55, 4.95 and 231.0 ppm). Such similarity in chemical shifts indicated that the sulfur-containing by-products, such as Ph$_3$SSAr and ArSSAr, which should be present in the solution, did not change the nature of alkoxy carbocation 21 appreciably.

The detailed mechanism for the reaction of 20 with ArS(ArSSAr)$^+$ (step 2) has not been clarified as yet, but 21 seems to be generated according to Scheme 9. Although the possibility of a single electron-transfer mechanism cannot be ruled out, ionic mechanism seems to be more plausible. In the ionic mechanism, ArS(ArSSAr)$^+$ acted as a thiophilic Lewis acid.

Scheme 9. Plausible reaction mechanism.
The reactions of thioacetals with conventional Lewis acids such as BF$_3$·OEt$_2$ and SnCl$_4$ do not give the corresponding alkoxycarbenium ions under similar conditions. Presumably such Lewis acids are not strong enough to generate alkoxycarbenium ions in a significant concentration. The equilibrium between 20 and 21 lies to 20 in such cases. In fact, Denmark and co-workers could not observe an alkoxycarbenium ion in low-temperature $^1$H NMR studies of a mixture of an acetal and a conventional Lewis acid, but they observed a Lewis acid–acetal complex.\textsuperscript{30}

Much lower reactivity of BF$_3$·OEt$_2$ was confirmed by the following experiments. The reaction of thioacetal 20 with BF$_3$·OEt$_2$ in 5 min followed by treatment with allyltrimethylsilane in 1 min at −78 °C did not give 22 in an appreciable amount (Scheme 10).\textsuperscript{31}

Scheme 10. Reaction of a thioacetal with BF$_3$·OEt$_2$.

As described above, the alkoxycarbenium ion generated by the indirect method exhibited NMR spectra similar to that generated by the direct method.\textsuperscript{25a} The thermal stability of the alkoxycarbenium ion generated by the indirect method was found to be also similar to that generated by the direct method. The cation pool generated at −78 °C was allowed to warm to a second temperature. After being kept there for 30 min, the pool was allowed to react with allyltrimethylsilane. Fig. 3, in which the yield of the product 22 is plotted against the temperature, indicates similar stability of the alkoxycarbenium ion generated by the direct method and that generated by the indirect method.\textsuperscript{25a}

Various carbon nucleophiles, such as allylsilanes, enol silyl ethers, ketene silyl acetics, and enol acetate are effective to give the corresponding C-C bond formation products (23-26) as shown in Scheme 11.

Fig. 3. Thermal stability of alkoxycarbenium ion 21 generated by the direct method and the present indirect method.

3.3 Reactions with thioacetals followed by reactions with alkenes. Synthesis of thiochromans

A pool of the alkoxycarbenium ion prepared by the "indirect cation pool" method reacts with stilbene derivatives to give thiochroman derivatives 34 (Scheme 12). In this case ArSSAr, which is present in the solution, participates in the reaction.\textsuperscript{32}

Scheme 12. The reactions of the alkoxycarbenium ion pool with stilbenes and ArSSAr (Ar = p-FC$_6$H$_4$).

The stereochemistry of the present reaction is interesting. The reaction with cis-stilbene gave 34 in 65% as a mixture of

![Diagram](image-url)
two diastereomers (d.r. = 2.6:1). The reaction of \textit{trans}-stilbene exhibited similar diastereoselectivity (70%, d.r. = 2.8:1). The diastereoselectivity indicates that the reaction proceeds by a step-wise mechanism rather than a concerted mechanism. The mechanism shown in Scheme 13 seems to be reasonable. Alkoxycarbenium ion 21 adds to the carbon-carbon double bond of stilbene to generate cation 35. Cation 35 reacts with ArSSAr to give intermediate 36. The elimination of MeO group in 36 generates cation 37, which cyclizes to give 34.

Scheme 13. The plausible reaction mechanism.

Various alkoxycarbenium ion pools (R = Ph, p-CI,C,H₄, PhCH₂CH₂, cyclohexyl) generated and accumulated from the corresponding thioacetals are effective for synthesizing substituted thiochromans (38-41) (Fig. 5).

Fig. 5 Synthesis of thiochroman derivatives by the reaction of alkoxycarbenium ion pools with \textit{cis}-stilbene and ArSSAr (Ar = p-FC₆H₄).

Because compounds having the thiochroman skeleton show interesting biological activities, several methods for synthesizing the thiochroman derivatives have been developed.\textsuperscript{33} For example, Ishibashi and co-workers reported the method based on the reaction of phenylthionium ion with olefins.\textsuperscript{34} Ishino and co-workers have developed the method based on intermolecular cycloaddition of \(\alpha,\beta\)-unsaturated aldehydes and thiophenols.\textsuperscript{35} Although these literature methods are based on the coupling of two different components, the present method is based on the coupling of three components, an alkoxycarbenium ion, a stilbene derivative, and ArSSAr, and therefore the present method serves as a more flexible way for constructing a thiochroman skeleton.

4 \textbf{Catalytic reactions}

A chain reaction is a sequence of the reaction, where a reactive product or by-product causes the next sequence to take place.\textsuperscript{46} Radical chain reactions\textsuperscript{72} are extensively studied so far. However, cationic chain reactions are not so popular in organic chemistry. Doyle and co-workers reported the first example of cationic chain reactions via hydride transfer.\textsuperscript{38} INIFER (INIFER-initiator transfer) method developed by Kennedy and Smith is also recognized as a cationic chain reaction.\textsuperscript{39} However, to the best of our knowledge, a cationic chain reaction mediated by organic cations such as ArS\textsuperscript{+} had not been developed when we initiated our studies on reactions using a catalytic amount of ArS\textsuperscript{+} as an initiator and a chain carrier.

4.1 \textbf{Cation chain reactions of involving cyclization of dienes}

We have already discussed the addition of ArSSAr to alkenes using a stoichiometric amount of ArS(ArSSAr)\textsuperscript{+}. The reaction proceeds by adding a soft quenching nucleophile such as Et,N (Scheme 4). If ArSSAr plays a role as a soft nucleophile, the last step regenerates ArS\textsuperscript{+}, which causes the next sequence to take place (Scheme 5, soft nucleophile = ArSSAr). If we use B(C₆F₅)₂ as a counter anion of ArS(ArSSAr)\textsuperscript{+}, this is the case. For example, (Z)-1-phenylpropene reacts with ArSSAr in the presence of a catalytic amount of ArS(ArSSAr)B(C₆F₅)₂ to give diarythio-substituted product (9 (Ar = p-FC₆H₄; 70%), 42 (Ar = p-MeOCC₆H₄; 59%)) (Scheme 14).\textsuperscript{40} The reaction of (E)-1-phenylpropene also gives the corresponding diarythio-substituted compounds (43 (Ar = p-FC₆H₄; 79%), 44 (Ar = p-MeOCC₆H₄; 77%)). It is important to note that the use of B(C₆F₅)₂ as a counter anion is essential for the success of this catalytic process. Therefore, Bu₄NB(C₆F₅)₂ as a supporting electrolyte should be used for the electrochemical oxidation of ArSSAr to generate ArS(ArSSAr)B(C₆F₅)₂.

Scheme 14. The reaction of 1-phenylpropenes with ArSSAr in the presence of a catalytic amount of ArS(ArSSAr)B(C₆F₅)₂.

With this information in hand, the cyclization reaction of non-conjugate dienes using a catalytic amount of ArS(ArSSAr)B(C₆F₅)₂ in the presence of ArSSAr has been developed (Scheme 15). For example, 1-phenyl-7-methyl-1,4-dimethyl-1,6-diene 45 reacted with 0.2 equiv of ArS(ArSSAr)B(C₆F₅)₂ in the presence of ArSSAr (Ar = p-MeOCC₆H₄). The cyclized product 46 was obtained in 77% yield as a mixture of two diastereomers, although compound 47 that would be formed via another mode of cyclization, was not obtained.\textsuperscript{31, 42} The observed cyclization mode is consistent with the nucleophilicity parameters reported by Mayr and co-
workers. According to their parameters, trialkyl-substituted alkenes are more nucleophilic than β-methylstyrene.

To the best of our knowledge, the present reaction is the first example that the addition of organic disulfide to non-conjugate dienes involving intramolecular carbon-carbon bond formation.

According to their parameters, trialkyl-substituted alkenes are more nucleophilic than β-methylstyrene.

To the best of our knowledge, the present reaction is the first example that the addition of organic disulfide to non-conjugate dienes involving intramolecular carbon-carbon bond formation.

The reaction seems to proceed by a mechanism shown in Scheme 16. The ArS" (= ArS(ArSSAr)+) reacts with the more nucleophilic carbon-carbon double bond in 45 to give episulfonium ion 48. The other carbon-carbon double bond attacks the episulfonium ion carbon to give cyclized cation 50, which reacts with ArSSAr to give 46. The final step regenerates ArS", which causes the next sequence to take place.

The benzylic ArS group in 46 could be selectively removed by the electrochemical reduction, which gave 51 as a single diastereomer (Scheme 17). This stereochemical information suggests that the cyclization proceeds by transition state 49 (Scheme 16), where a carbon-carbon double bond attacks the episulfonium ion from the back side.

The stereochemistry of the carbon-carbon double bond in 45 does not affect the diastereoselectivity of the cyclization (Scheme 18).

Other non-conjugate dienes such as 52, 54, and 56 also reacted in a similar manner to give the corresponding cyclized products (53, 55, and 57) (Scheme 19).

The reaction of a catalytic amount of ArS(ArSSAr)+B(C6F5)4 with 54 in the presence of ArSSAr followed by addition of allyltrimethylsilane instead of Et3N led to the selective formation of olefinic product 58 (Scheme 20). Presumably, ArS" that remained in the solution reacted with allyltrimethylsilane to produce highly reactive Me3Si+, which reacted with 55 to cleave C-S bond generating the tertiary carbocation. β-Proton elimination gave 58. The resulting proton reacted with allyltrimethylsilane to regenerate Me3Si+.
It is noteworthy that the direct (in-cell) electrolysis of a diene in the presence of ArSSAr was also effective to initiate the reaction. Thus, a catalytic amount of electricity was passed through a solution of 45 (0.30 mmol) and ArSSAr (1.0 mmol) (0.20 F/mol based on 45). After the electrolysis, the reaction mixture was stirred for 0.5 h to obtain the cyclized product 46 in 82% yield (d.r. = 1.1 : 1). This method can be applicable to other dienes such as 52, 54, and 56 to obtain the corresponding cyclized products (53, 55, and 57).

4.2 Cation chain reactions involving cyclization of olefinic thioacetals

In 3.2, we discussed the formation of alkoxycarbenium ions by the reaction of thioacetals with ‘ArS’–. The cationic chain reaction involving this process has also been developed.60 The general reaction scheme is shown in Scheme 21. The reaction of an alkoxycarbenium ion, which is generated by action of a thioacetal with ‘ArS’–, with an olefin leads to the formation of the second cation.31 The reaction of the second cation with ArSSAr gives sulfenylated product to regenerate ‘ArS’2–. ‘ArS’2– would act as an activator of another molecule of the thioacetal. Therefore, the overall reaction should take place with a catalytic amount of ‘ArS’–.

Scheme 21. The cation chain reactions involving the formation of alkoxycarbenium ion.

There are several points to be considered.31 The formation of the alkoxycarbenium ion takes place quantitatively as we discussed in 3.2. However, the reaction of the alkoxycarbenium ion with an olefin might be unfavorable because the second cation does not have a neighboring cation stabilizing group such as an oxygen atom, and this step might be a bottle-neck of the overall reaction.61 The last step to form a stable product from the unstable second cation, however, could be energetically favorable, making the overall reaction successful. Another important point to be considered is that the second step could be made entropically favorable by the intramolecularization of the reaction.

The concept works. For example, treatment of thioacetal 59 (R = C7H15, Ar = p-FC6H4) bearing a carbon-carbon double bond with 0.2 equiv of ArS(ArSSAr)2B(C6F5)4 (Ar = p-FC6H4) at −78 °C led to the formation of cyclized compound 60 (82%) (Scheme 22).65 In this case, ArSSAr (1.00 mmol) was electrolyzed with 0.04 F/mol of electricity in Bu4NB(C6F5)4/CH2Cl2 at −78 °C, and the resulting solution containing ArS(ArSSAr)2B(C6F5)4 (0.04 mmol) and ArSSAr (0.94 mmol) was allowed to react with 59 (0.2 mmol).

Scheme 22. The cyclization of olefinic thioacetals with a catalytic amount of ArS(ArSSAr)2B(C6F5)4.

In section 4.1, we discussed cationic chain reactions of dienes involving intramolecular carbon-carbon bond formation, which is net addition of ArSSAr to dienes. In contrast, this reaction is net isomerization. A cationic chain mechanism shown in Scheme 23 seems to be reasonable.

Scheme 23. Mechanism of cationic chain reaction of olefinic thioacetals mediated by ‘ArS’–.

High stereoselectivity observed (exclusive formation of the cis isomer) indicates that the carbon-carbon bond formation and the subsequent reaction of the resulting cation with ArSSAr take place in somewhat concerted manner. The fact that use of an excess amount of ArSSAr accelerated the reaction is consistent with this mechanism. At higher concentrations of ArSSAr, this step becomes more favorable and hence the overall reaction is accelerated.

The reaction is generally applicable to various olefinic thioacetals bearing a carbon-carbon double bond (61, 63, 65, 67, 69, and 71) to give the corresponding cyclized products (62, 64, 66, 68, 70, and 72) as shown in Scheme 24. The present method is useful to construct a tetrahydropyran ring that serves as a popular structural unit in a variety of biologically interesting molecules.69 It is also noteworthy that the ArS group could be used for further transformations.
Scheme 24. Intramolecular carbon-carbon bond formation mediated by ArS(ArSSAr)B(C_6F_5)_2.

The in-cell method is also effective. The electrolysis of a mixture of an olefinic thioacetal bearing a carbon-carbon double bond and ArSSAr gives the corresponding cyclized product. The reaction is usually conducted by passing a catalytic amount of electricity (0.20 F/mol based on thioacetal) through a solution of an olefinic thioacetal (0.2 mmol) and ArSSAr (1.0 mmol) in 0.1 M Bu_NNB(C_6F_5)_2/CH_2Cl_2 at –78 °C under constant current conditions, and after the electrolysis the reaction mixture is stirred for 20 min to obtain the corresponding cyclized product.

5 Conclusion

Low-temperature electrochemical oxidation of ArSSAr generates ArS”+, which has been characterized as ArS(ArSSAr)H based on spectroscopic studies such as CSI-MS and 1H NMR analysis. The resulting ArS(ArSSAr)+ reacts with carbon-carbon multiple bonds to give diarylthio-substituted compounds and thiofluorinated compounds. ArS(ArSSAr)+ also serves as an effective reagent for rapid generation of alkoxy carbencium ion pools from thioacetals at –78 °C. The resulting alkoxy carbencium ion pools react with carbon nucleophiles to give the corresponding carbon-carbon bond formation products (indirect cation pool method). The reactions of alkoxy carbencium ions with stilbene derivatives give thiochroman derivatives. In addition to these stoichiometric reactions, ArS(ArSSAr)+ also promotes catalytic reactions such as cationic chain reactions. For example, the treatment of dienes with a catalytic amount of ArS(ArSSAr)+ in the presence of ArSSAr leads to net addition of ArSSAr involving intramolecular carbon-carbon bond formation, providing a new type of time and space integration of carbocationic reactions. The reaction of olefinic thioacetals also gives cyclized products. The in-situ generation of a catalytic amount of ArS” is also effective for the cationic chain reactions. These stoichiometric and catalytic reactions demonstrate that the electrochemically generated ArS” opens a new aspect of chemistry of organic cations and synthetic transformations utilizing organic cations.

Acknowledgments

This work was financially supported in part by a Grant-in-Aid for Scientific Research from the Japan Society for the Promotion of Science. We are deeply grateful to Nippon Shokubai Co. and Nippho Chemicals Co. for providing NaB(C_6F_5)_4 as a precursor of Bu_NNB(C_6F_5)_2. We also thank Prof. Hendrik Zipse of Ludwig-Maximilians-Universität in München for fruitful discussions. K.M. acknowledges JSPS for financial support.
