ABSTRACT

Rev-erbα, a component of the circadian clock, has also been known as a nuclear receptor that lacks activation function domain 2, functioning as a ligand-dependent transcriptional repressor. However, we recently reported that Rev-erbα activates connexin43 transcription by forming a complex with Sp1. Here we show that heme, a REV-ERB ligand, is dispensable for this novel mechanism and that Rev-erbβ, having homologies with Rev-erbα, does not activate connexin43, but competes with the Rev-erbα/Sp1. The A/B region of Rev-erbα, which is not conserved in Rev-erbβ, is a crucial activating domain, while the ligand binding domain, conserved in Rev-erbβ, functions as a competitor.

Key words: Connexin43/Nuclear receptor/Rev-erbα/ Rev-erbβ /Sp1

Abbreviations: connexin43, Cx43; A/B region, AB, DNA binding domain, DBD; hinge region, H; ligand binding domain, LBD; Estrogen Receptor, ER
INTRODUCTION

Rev-erbα and Rev-erbβ, initially identified as orphan nuclear receptors Nr1d1 and Nr1d2, are also components of the circadian clock, have important roles in metabolism and cellular differentiation [1-4]. The circadian clock is genetic machinery that generates autonomous genetic oscillations in systemic organs by coordination of transcriptional activators (Bmal1 and Clock) and repressors (Per1–3 and Cry1, 2) that regulate other genes by binding to E boxes in promoter regions [5,6]. Concurrently, Rev-erba/β and Rora/β/γ has been shown to tune the amplitude and the phase of the circadian clock, or control transcription of other non-clock genes, by binding to RORE sites of target genes [1,3,7,8].

Nuclear receptors modulate transcriptional activity by binding to specific ligands such as steroid hormones, thyroid hormone, vitamin D and retinoids, and function either as activators or repressors by recruiting co-activators or co-repressors, respectively [9,10]. Rev-erba and Rev-erbβ have been considered to be ligand-dependent transcriptional repressors since they lack a canonical activation function domain 2 (AF-2) [11,12] and their repressive effects by recruiting nuclear receptor co-repressor/histone deacetylase 3 depend on their ligand of heme [13-16].
However, in a sharp contrast to these previous notions, we have revealed that Rev-erbα functions as an activator for connexin43 gene (Cx43) by forming a complex with Sp1 in HEK293T cells and bladder smooth muscle cells [17]. Importantly, this effect required proximal Sp1 sites, but no RORE sequences, on the Cx43 promoter.

Sp1 is an Sp/KLF family transcriptional factor that regulates expression of multiple genes with GC-rich sequences, i.e., Sp1 binding sites, on their promoter regions [18,19]. The Sp1-dependent transactivation of GC-rich promoter sequences is reported with various nuclear proteins as well as basal transcription factors [11]. Interaction between Sp1 and nuclear receptors are reported with RAR, RXR, ERs and PPAR, which possess common structures of nuclear receptor domains including an A/B region (AB), a DNA binding domain (DBD), a hinge region (H) and a ligand binding domain (LBD) [20-22].

Here, we investigate the detailed mechanism by which Rev-erbα and Sp1 complex to transactivate the Cx43 promoter in comparison with Rev-erbβ, and clarify the roles of Rev-erbα domains for the process.
METHODS

Plasmid constructs. The mouse pGL-2-Cx43 promoter-reporter (pCx43-1686/+165-luc), constructed by Dr. S.J. Lye [23], was a kind gift from Dr. J. Yao (University of Yamanashi, Yamanashi, Japan). The pRL-TK (Promega, Madison, WI) were used as a transfection efficacy control. The Sp1 expression vector, constructed by Dr. Suske [24] was a kind gift from Dr. Toguchida (Frontier Medical Sciences, Kyoto University, Kyoto, Japan). The expression vector of Rev-erbα and Rev-erbβ was purchased from Open Biosystems (Huntsville, AL). Site-directed mutagenesis, deletion and addition of aimed sequences were performed using a mutagenesis basal kit (Takara) according to the manufacturer’s protocol. These mutants were all verified by sequencing.

Promoter-reporter assay. Reporter plasmids with various expression vectors were transfected into HEK293T cells in 24-well plates using Fugene6 (Roche) in DMEM with 10% fetal calf serum (FCS) according to the manufacturer’s protocol. pCx43-luc or pGL2-basic 100 ng and pTK-RL 5 ng were transfected with various amounts of expression vectors (total 250 ng). Plasmid dosage was kept constant by EGFP-N1 vector. Lysates were harvested 48 hours post-transfection, and the luciferase activity was measured using a dual luciferase assay reagent (Promega). For the hemin treatment, medium was changed to various concentration of hemin in DMEM with 10% FCS at 24 hour after the transfection and kept for 24 hour. For SR8278 (Sigma) and GSK4112 (Sigma) treatment, 24 hours after the transfection medium was changed to DMEM with 10% FCS containing 10μM of each reagent and incubated for additional 24 hours.
**Immunoblotting.** Preparation of whole-cell lysates from HEK293T cells, and the immunoblotting procedure were performed as previously described [17,25]. Briefly, cells were lysed in radio-immunoprecipitation assay (RIPA) buffer containing protease inhibitors. The protein content of the cell lysates was measured using the BioRad Protein Assay Kit. Cell lysates were resolved by sodium dodecyl sulfate polyacrylamide electrophoresis and transferred to an Immobilon-P membrane (Millipore, Bedford, MA). The membranes were incubated with antibodies for Sp1 (Millipore, Milford MA, 1:2000), HA (Abcam, 1:8000), DDDDK (MBL, Aichi, Japan 1:2000), Rev-erbα (Cell Signaling Technology [CST], Beverly, MA, 1:500), Cx43 (Sigma, St Louis, MO, 1:1000), Bmal1 (Santa Cruz Biotechnology, Santa Cruz, CA 1:200) and GAPDH (CST, 1:2000). The Rev-erbα antibody of CST (2124) was for 20 amino acids between 200 and 300 from the N terminus, including the H region. After incubation with HRP-conjugated anti-rabbit or anti-mouse secondary antibodies (Pierce, Rockford, IL), immunoreactive proteins were visualized using a Super Signal West Pico Chemiluminescent Substrate (Pierce, Rockford, IL).

**Co-immunoprecipitation assay.** Preparation of nuclear extracts and
co-immunoprecipitation were performed as previously described [17]. Briefly nuclear extracts were prepared from HEK293T cells in 10 cm dishes, transfected with HA-Rev-erbα or HA-Rev AB (3.75 µg), and DDDDK-Sp1 (3.75 µg) expression vectors for 48 hours, using Nuclear Complex Co-IP kit (Active Motif, Carlsbad, CA). The 100 µg of nuclear extracts were incubated with 4 µg of antibodies for HA and control rabbit IgG (Zymed) in 500 µl of low IP buffer overnight at 4 °C with rotation followed by addition of 30 µl of Dynabeads Sheep anti-Rabbit IgG (Veritas, Tokyo, Japan) for 1 hour. After washing with low IP buffer, the binding protein was eluted in 40 µl of RIPA buffer for immunoblotting. The 2 µg of nuclear extracts were used as input.

Statistical analysis. We used one-way ANOVA followed by Tukey’s post-hoc test for the multiple comparisons or by Dunnett’s post-hoc test for comparing to the control in the promoter-reporter assay, calculated with SPSS ver.11.0.1J software (SPSS Inc., Chicago, IL). A $P$ value < 0.05 was accepted as significant.

RESULTS AND DISCUSSION

Ligand is dispensable for activation by Rev-erbα with Sp1

Firstly, to investigate whether the transactivation of $C_{x43}$ promoter by
Rev-erbα/Sp1 complex is controlled by heme, the ligand of Rev-erbα as a nuclear receptor, we applied various concentrations of heme to the HEK293T cells transfected with Rev-erbα/Sp1. Exogenously applied heme showed little impact on the *Cx43* promoter activation (Fig. 1A), while it enhanced the suppressive effect on the abundance of Bmal1 protein as reported (Fig. 1B) [13,15]. In addition, SR8278, an antagonist of REV-ERB, was applied to block the action of endogenous agonist heme, which is always present in the cells [26]. It also had little effect on the *Cx43* promoter activation, which was not influenced by addition of GSK4112, an agonist of REV-ERB (Supplementary Fig. S1). Notably, although the ligand binding domain (LBD) of Rev-erbα has been reported to be crucial for recruiting co-repressors [14,15], a deletion mutant of LBD of Rev-erbα (Rev ΔLBD) still retained transactivation activity for the *Cx43* promoter (Fig. 1C). In contrast to the suppressive effect of Rev-erbα, the ligand is not considered to play a significant role in the transactivation mechanism.

**Rev-erbβ competes with Rev-erbα and Sp1 complex**

Next, to investigate whether Rev-erbβ transactivates the *Cx43* promoter in a similar manner as Rev-erbα with Sp1, we drove expression of Rev-erbβ in conjunction with a *Cx43* promoter-reporter. However, Rev-erbβ scarcely affected the promoter
activity of Cx43 even when co-expressed with Sp1 (Fig. 2A). Intriguingly, Rev-erbβ competed with Rev-erbα in the presence of Sp1 for the transactivation of the Cx43 promoter (Fig. 2B). This result is completely different from the previous notion that Rev-erbα and Rev-erbβ have nearly identical functions in the liver [27]. These results prompted us to investigate the precise mechanism of Cx43 promoter transactivation by Rev-erbα with Sp1.

The A/B region of Rev-erbα is an activation domain.

Alignment comparison of Rev-erbα with Rev-erbβ disclosed that they have a different A/B region but a similar DNA binding domain (DBD), a hinge region (H) and a C terminal region of their LBD (Supplementary Fig. S2). According to their similarities and differences, we generated various domain oriented deletion mutants of Rev-erbα to examine the domains responsible for the activation of Cx43 (Fig. 3A). The promoter-reporter assay revealed that, a part of the N terminal region of Rev-erbα (8-49) and the LBD were not crucial for the activation of the Cx43 promoter, while the A/B region, DBD and H region were indispensable (Fig. 3B). These effects were also confirmed at the protein level by immunoblotting (Fig. 3C). In accordance with previous reports [1,14], wild-type (WT) Rev-erbα successfully suppressed Bmal1
protein expression. Notably, in contrast to the transactivation of the Cx43 promoter, co-transfection of a deletion mutant of the A/B region (ΔAB) still had a suppressive effect on Bmal1 expression, while those with deletions of the DBD, H region or LBD (ΔDBD, ΔH and ΔLBD) failed to suppress it.

In light of these results, we focused on the A/B region as an activation domain and generated a DNA construct for expression of this region alone (HA-Rev AB). Indeed, the HA-Rev AB still transactivated the Cx43 promoter transfected with Sp1 (Fig. 3D) and the HA-Rev AB was co-immunoprecipitated with Sp1 (Fig. 3E).

**The LBD of Rev-erbα is a competition domain.**

Rev ΔAB, a mutant Rev-erbα without A/B region, not only failed to activate, but inhibited the transactivation of Cx43 promoter by Rev-erbα with Sp1 in a dose dependent manner (Fig. 4A), indicating that Rev ΔAB contains a competition domain for Rev-erbα/Sp1 complex to transactivate the Cx43 promoter.

To identify the competition domain of Rev-erbα, we assessed the effect of Rev ΔH, Rev DBDLBD (a mutant of Rev-erbα only with the DBD and LBD) or Rev DBD (a mutant of Rev-erbα only with the DBD) with Rev-erbα/Sp1 (Supplementary Fig. S3). The competition was observed in Rev ΔH and Rev DBDLBD but not in Rev DBD,
indicating that not the H region or DBD but the LBD could be the required domain. Indeed, Rev LBD (a mutant of Rev-erbα only with LBD) competed with the Rev-erbα/Sp1 (Fig. 4B). Therefore, the LBD is involved in the transactivation of the Cx43 promoter by Rev-erbα/Sp1 complex as a potential competition domain.

Thus, different amino acid arrangements in the A/B activation domain regions of Rev-erbα and Rev-erbβ may underlie their differential activation of the Cx43 promoter. Conversely, high compatibility in LBD between these two Rev-erb subtypes may underlie the competitive effect of by Rev-erbα by Rev-erbβ (Fig. 4C). We should note that this relationship between Rev-erbα and Rev-erbβ is similar to the relationship between Estrogen Receptor (ER) α and ERβ. The importance of the A/B region of nuclear receptors for associating with Sp1 has also been postulated for this ER family. Saville and coworkers reported that the ERα possesses a transactivation function, but ERβ does not, while a chimeric ERα/β, possessing the A/B region of ERα and other domains of ERβ, also has a transactivation function on a 17-beta Estradiol 2-responsive construct containing a GC-rich promoter [28]. ERα and ERβ are also competitive on the Sp1 site of the promoter [28]. Li and coworkers demonstrated that amino acids 67-139 of ERα, a part of the A/B region, were sufficient for the transactivation by ERα/Sp1 [29].
The physiological implication of this novel competitive role for Rev-erbβ is unclear. Rev-erbβ is also a component of the circadian clock [27,30] and oscillates in the urinary bladder (Supplementary Fig. S4), thus one could speculate that Rev-erbβ tunes the circadian expression of Cx43 by competing with Rev-erba. Because the peak expression of Rev-erbβ is 3.6 h later than Rev-erba, followed by Cx43 (Supplementary Fig. S4) in the urinary bladder, Rev-erbβ may contribute to decrease the transactivation of Cx43 after the peak point. Since the present study relies to a large extent on overexpression and reporter assays, physiological relevance and functional significance of the findings still remains to be determined.

As other limitation of the present study, we showed the specific role of Rev-erba domains for transactivation of the Cx43 promoter, but not the specific amino acid sequence required for the activation by Rev-erba/Sp1 complex. The molecular structure of the complex, including the detailed interaction with Sp1 and other co-activators and/or co-repressors, which may also induce differences in effect of Rev-erba/β [31-34], remains to be investigated to elucidate the entire mechanism of this novel transcription complex.

In summary, the present study shows that heme as the ligand is dispensable for transactivation of the Cx43 promoter by Rev-erba with Sp1, and that the A/B region of
Rev-erbα functions as an activation domain, while the LBD of Rev-erbα is a competition domain. This mechanism may underlie the competitive effect by Rev-erbβ on the transactivation. These findings provide a new insight into interaction between the clock regulator/nuclear receptors and Sp1.
