Introduction

First synthesized by Natta et al. in 1958, polyacetylene (1) has attracted much attention, both in its synthesis and properties. The trend has been accelerated in particular since the synthesis of a uniform polyacetylene film by Shirakawa et al. with use of Ti(O-n-Bu)₄·Et₃Al catalyst. The most salient feature of polyacetylene is the electrical conductivity that arises from conjugation of the main-chain which contains alternating double bonds, and reaches the metallic region upon doping. Despite such interesting properties, however, the polymer is insoluble, infusible, and unstable in air, making its manipulation, fabrication, and application difficult.

In sharp contrast to the extensive synthetic efforts for 1, the synthesis of high polymers from substituted acetylenes had been difficult for a long time, until Masuda and Higashimura found in 1974 that phenylacetylene (2) could be polymerized with WCl₆ and MoCl₅ to form high polymers. It has been revealed that group 6 transition metal halides (WCl₆, MoCl₅, etc.), either alone or in conjunction with suitable cocatalysts (e.g., Ph₄Sn), provide high-molecular-weight polymers particularly from acetylenes having bulky substituents (eq. 1). Since then, various monosubstituted and disubstituted acetylenes have been polymerized with those catalysts as well as NbCl₅- and TaCl₅-based catalysts. Unlike the unsubstituted counterpart (1), some of these substituted polyacetylenes are soluble in various organic solvents and have weight-average molecular weights ($M_w$) around $1 \times 10^6$. 

$$\begin{array}{c}
\text{CH} = \text{CH} \quad 1 \\
\text{HC} = \text{C} \end{array}$$
It was claimed\textsuperscript{5} that the transition metal-mediated polymerization of substituted acetylenes follows a metathesis polymerization mechanism as shown in eq. 2 like ring-opening polymerization of cycloolefins\textsuperscript{6}; i.e., the monomer coordinates to a metal carbene, which contains a carbon-metal double bond, to form a metallacyclobutene that subsequently cleaves to regenerate a metal carbene.

\begin{equation}
\text{C} = \text{M} \langle \text{C} = \text{C} \rangle \rightarrow \text{C} = \text{M} \langle \text{C} = \text{C} \rangle
\end{equation}

Previous investigations have disclosed the following relationships between monomer structure and polymerization behavior of substituted acetylenes:\textsuperscript{7} i) Monosubstituted derivatives and disubstituted acetylenes carrying relatively small substituents polymerize with group 6 transition-metal (Mo, W) catalysts, whereas disubstituted acetylenes carrying bulky substituents with group 5 transition-metal (Nb, Ta) catalysts; ii) High-molecular-weight polymers are difficult to form from acetylenic monomers containing heteroatoms like oxygen and nitrogen with lone pair electrons; iii) The molecular weight of the polymers increases with increasing bulkiness of the substituents, though no polymerization occurs if the substituents are too bulky. More data should, however, be collected to predict the relationship between monomer structure and its reactivity.

It has also been revealed that substituted polyacetylenes show unique properties that clearly differ from those of polyacetylene. For example, substituted polyacetylenes are soluble in various organic solvents thanks to the interaction between their substituents and solvent. The extent of the main-chain conjugation is lower than in polyacetylene because the backbone is twisted by the bulky substituents. Thus, substituted polycyacetylenes exhibit colors ranging from purple to white and are stable in air. Another interesting property is the high gas permeability. This is noteworthy, particularly because these polymers are glassy at room temperature. Especially, poly[1-(trimethylsilyl)-1-propyne] [3, poly(TMSP)] is the most gas-permeable among the hitherto known synthetic polymers,\textsuperscript{8} and therefore its gas permeation behavior has been intensively studied.

Among a number of substituents that can be incorporated in acetylenic monomers silicon- and fluorine-based groups are of particular interest in terms of polymerization mechanism and polymer properties. For examples, silicon- and fluorine-containing polymers, in general, are known to show unique properties.\textsuperscript{9} The features of silicon-containing polymers include high thermal stability, high resistance to reactive ion etching (suited for photo-resists), and high gas permeability as demonstrated in poly(dimethylsiloxane). Fluorine-containing polymers are characterized by high thermal stability, resistance to chemicals, and unique solubility.\textsuperscript{10}

In view of the facts discussed above, silicon- and fluorine-containing acetylenes are heteroatom substituted acetylenes of particular interest in terms of both their polymerization behavior and polymer properties that should differ from those of hydrocarbon polyacetylenes. However, the synthesis of such polyacetylenes has not been attempted very much. Thus, the author decided in the present study to examine the polymerization and polymer properties of silicon- and fluorine-containing acetylenes, to specifically focusing on the relationship between monomer structure and either polymer yield or molecular weight and on the synthesis of polymers with unique properties.
For these research objectives, the author selected a series of silicon- and fluorine-containing acetylenes: the trialkylsilyl groups (typically trimethylsilyl, SiMe$_3$) in the monomers 4 - 9 are bulky and slightly electron-donating. On the other hand, the fluorine-containing groups in 11 and 12 are relatively compact and strongly electron-withdrawing. Thus, it is expected that the steric and electronic effects of substituents on polymerization become clear if the polymerization of silicon- and fluorine-containing acetylenes is examined. Equally important, these acetylenic monomers may be useful to clarify the relationship between the kind of pendant group and polymer properties.

This thesis consists of three parts. Part I and Part II deal with the polymerization and polymer properties of the silicon-containing acetylenes (4 - 9), while Part III concerns those of fluorine-containing acetylenes (11 and 12).

Part I delineates the polymerization of aromatic disubstituted acetylenes (4 - 6) having various silyl groups and their polymer properties, especially gas permeability.

Chapter 1 deals with diphenylacetylenes (4) carrying an SiMe$_3$ group at the para or meta position on one of the phenyl groups. Silylacetylenes 4 were polymerized by TaCl$_5$-cocatalyst systems to form in good yield new polymers whose $M_w$ exceeded over 1$x$10$^6$. Their polymerization behavior was similar to that of diphenylacetylene without an SiMe$_3$ group. The polymers were soluble in toluene and CHCl$_3$ owing to the presence of the SiMe$_3$ group, whereas poly(diphenylacetylene), free from a silyl group, is insoluble in any solvents. Free-standing films could be obtained from poly(4) by solution casting. The on-set temperatures of weight loss were over 400 °C, indicating a fairly high thermal stability of the polymers.

Chapter 2 treats monomers 5, which have bulky substituents on the silicon of 4. The $M_w$ of the polymers obtained from 5 with TaCl$_5$-cocatalyst reached several hundred thousand. The polymer yields for the para isomers were similar to those of 4, while those for the meta isomers were smaller because of the steric hindrance of the meta-substituents. Most of the polymers were soluble in various organic solvents, whereas the polymers with very bulky substituents on the para silyl group were not.

Chapter 3 describes the polymerization of monomer 6, which has a methyl group instead of a phenyl group in 4. Not only TaCl$_5$ but also NbCl$_5$ produced polymers from 6. The polymer was soluble in various organic solvents and had high molecular weight over 1x10$^6$. When 1-phenyl-1-propyne, an SiMe$_3$ free parent form of 6, is polymerized by NbCl$_5$ and TaCl$_5$ alone, polymer degradation occurs after the polymerization. No degradation was, however, observed for 6, showing that introduction of a bulky SiMe$_3$ group inhibits such a polymer degradation. During the polymerization of 6, the molecular weight of polymer increased approximately in proportion to monomer conversion. This indicates the presence of a long-lived propagating species.

In Chapter 4, the gas permeability of the silicon-containing polymers synthesized in this thesis was examined. Poly(4)s were found to show very high gas permeability of ca. 1/4 the value of poly(TMSP) and of about two-fold that of poly(dimethylsiloxane). The gas permeability of the substituted polyacetylenes depended on the structure of the substituents. It was revealed that bulky
substituents on the silicon atom tended to reduce gas permeability.

Part II discusses the polymerization and polymer properties of monosubstituted acetylenes with bulky silyl groups. Chapter 5 concerns monomer 7, which has an SiMe₃ group at the ortho position of phenylacetylene. A high polymer was obtained from 7 by using WCl₆- and MoCl₅-based catalysts. The $M_w$ of polymer reached 1x10⁶, although that of poly(phenylacetylene) generally remains below 1x10⁵. This difference is due to the steric effect of the ortho-substituent. The propagating species formed from WCl₆- and MoCl₅-cocatalyst were long-lived. The polymer was a purple solid with UV-visible absorption red-shifted relative to poly(phenylacetylene).

Chapter 6 describes monomer 8, which has a bulky substituent on the silyl group of 7. Practically no change was observed in the yield, molecular weight, or UV-visible absorption of the polymer compared with poly(7), despite of the presence of the ortho-substituent bulkier than SiMe₃.

Chapter 7 presents 1-hexynes (9) with bulky silyl groups at the carbon adjacent to the C=C bond. Monomers 9 gave polymers with $M_w$ of 2x10⁵ - 4x10⁵ in the presence of WCl₆ and MoCl₅. The polymers dissolved in various organic solvents, though poly(10), which has an SiMe₃ group at the same position, is partly insoluble in common organic solvents. The polymerization behavior of 9 was similar to that of 10. The WCl₆-cocatalyst and MoCl₅-cocatalyst systems led to long-lived propagating species.

Part III is focused on the polymerization and polymer properties of fluorine-containing acetylenes.

In Chapter 8 was examined the polymerization of a phenylacetylene (11) carrying two CF₃ groups, which is an example of fluorine-containing aromatic acetylene. W, Mo, and Nb catalysts produced polymers from 11 in high yield. The polymers were soluble only in $p$-(CF₃)₂C₆H₄, where the highest intrinsic viscosity was 0.35 dL/g, suggesting that the polymers have higher molecular weights than poly(phenylacetylene). This is probably due to the steric effect of CF₃ groups rather than the electronic effect. The on-set temperature of weight loss in air was relatively high (ca. 300 °C).

Chapter 9 discusses aliphatic monomers 12 as examples of monosubstituted acetylenes with perfluoroalkyl groups. Polymers were obtained in fair yields from 12 with the WCl₆-Ph₄Sn catalyst. They were soluble in hexafluorobenzene (intrinsic viscosity ~0.05 dL/g) and had rather low molecular weight like poly(1-alkynes).

In the present doctoral study, the author synthesized new silicon- and fluorine-containing polyacetylenes and found the remarkable effects of the silicon- and fluorine-containing group on the polymerization and polymer properties, such as gas permeability. It is noteworthy that among the polymers, poly(4)s exhibit very high gas permeabilities. It is desired that novel substituted polyacetylenes will be synthesized further and that the effect of substituent on polymerization and polymer...
Properties of acetylenes will be clarified for designing new, unique specialty polymers.

Chapter 1

Polymerization and Polymer Properties of Silicon-Containing Diphenylacetylenes

Abstract

Poly(diphenylacetylene) is thermally very stable, but insoluble in any solvents, whereas polyacetylenes from unsymmetrically disubstituted acetylenes are generally soluble. Hence the synthesis of soluble poly(diphenylacetylenes) was examined by introducing the trimethylsilyl group. 1-Phenyl-2-p-(trimethylsilyl)phenylacetylene and 1-phenyl-2-m-(trimethylsilyl)phenylacetylene polymerized with TaCl₅-cocatalyst systems to provide new polymers over 70% yields having weight-average molecular weight over 1x10⁶. As cocatalysts, n-Bu₄Sn, Et₃SiH, and 9BBN were especially effective. The polymers were yellow solids with the alternating double bond structure, [-CPh=C(C₆H₄-SiMe₃)-]ₙ. As expected, they completely dissolved in toluene, CHCl₃ etc., and formed free-standing films by solution casting. The temperatures at which their weight loss started in TGA were as high as ca. 400 °C.
Introduction

Various substituted polyacetylenes have recently been synthesized by group 5 and 6 transition-metal catalysts. Among these polymers, poly(diphenylacetylene) [poly(DPA)] is obtained in good yields with TaCl₅-cocatalyst systems, and exhibits the highest thermal stability among substituted polyacetylenes (the temperature at which its weight loss starts in air is ~500 °C). This polymer, however, does not dissolve in any solvents. In general, polymers from symmetrically disubstituted acetylenes tend to be insoluble in solvents. For instance, poly(2-octyne) and poly(3-octyne) are soluble in common organic solvents, whereas poly(4-octyne) is not. Hence, if a bulky substituent is introduced into one phenyl group of diphenylacetylene (DPA), a soluble polymer is anticipated to form.

Among many unique properties of substituted polyacetylenes, the most striking one is their high gas permeability. Especially, silicon-containing polyacetylenes are likely to show high gas permeability. As an extreme example, the permeability of poly[1-([trimethylsilyl]-1-propyne] [poly(TMSP)] to oxygen is higher than any other existing polymers, and has recently been under intensive research.

From the viewpoints stated above, it is expected that poly(DPA)s having a trimethyisilyl group on one phenyl group will be soluble in organic solvents, and will exhibit high thermal stability and high gas permeability. Further, it is of interest to examine the influence of the trimethyisilyl group on polymerization behavior. To clarify these points, the polymerization and polymer properties of 1-phenyl-2-[p-(trimethylsilyl)phenyl]acetylene (p-Me₃SiDPA) and 1-phenyl-2-[m-(trimethylsilyl)phenyl]acetylene (m-Me₃SiDPA) have been investigated in this chapter.

Results and Discussion

Polymerization by Various Catalysts

Polymerization of p-Me₃SiDPA was studied by using group 5 and 6 transition metal catalysts which are effective in the polymerization of various substituted acetylenes (Table I). Though p-Me₃SiDPA was consumed to some extent with TaCl₅ alone, no methanol-insoluble polymer was produced. On the other hand, polymers were obtained when organometallic cocatalysts that are effective in the polymerization of DPA were added in a two-fold excess to TaCl₅. Especially, n-Bu₄Sn, Et₃SiH, and 9BBN achieved almost quantitative monomer conversions.

and polymers were obtained in over 70% yields. When n-BuLi and vitride were used as cocatalysts, on the contrary, the monomer did not react so much, and the polymer yields remained low. These cocatalysts, which are weak reducing agents, are considered to help initiation reaction and to modify the propagating species. All the polymers produced were soluble in toluene and CHCl₃ unlike poly(DPA). Many of the weight-average molecular weights (Mₜ/w) of polymers exceeded 2x10⁶ according to gel permeation chromatography (GPC; a polystyrene calibration).

No polymer was obtained from p-Me₃SiDPA with NbCl₅-n-Bu₄Sn (see Table I), though this catalyst is effective in the polymerization of dissubstituted acetylenes like 1-phenyl-1-propyne and 1-(trimethylsilyl)-1-propyne. WCl₆-n-Bu₄Sn and MoCl₅-n-Bu₄Sn, which polymerize various substituted acetylenes, gave no polymer, either. The methanol-soluble products (differences between the monomer conversions and the polymer yield in Table I) were all linear oligomers according to GPC (several sequential peaks below molecular weight 1000).

The polymerization of m-Me₃SiDPA was examined using various catalysts (Table II). When TaCl₅ was employed in conjunction with suitable cocatalysts such as n-Bu₄Sn, Et₃SiH, and 9BBN, the yields of methanol-insoluble polymers exceeded 70%. The Mₜ/w values of the polymers were 1x10⁶ and above. n-BuLi and vitride were less effective as cocatalysts, as is judged from the polymer yields and molecular weights. Further, none of TaCl₅ alone, NbCl₅-n-Bu₄Sn, WCl₆-n-Bu₄Sn, and MoCl₅-n-Bu₄Sn catalysts produced any methanol-insoluble polymer. Thus, m-Me₃SiDPA behaves in polymerization similarly to p-Me₃SiDPA and DPA, although the molecular weight of poly(m-Me₃SiDPA) is somewhat lower than that of poly(p-Me₃SiDPA).

**Polymerization with TaCl₅-n-Bu₄Sn**

Effects of polymerization conditions were studied by using TaCl₅-n-Bu₄Sn which proved to be one of the most effective catalysts in the polymerization of p-Me₃SiDPA and m-Me₃SiDPA. Solvent effect on the polymerization of p-Me₃SiDPA and m-Me₃SiDPA by TaCl₅-n-Bu₄Sn was studied (Table III). The polymerization of both monomers proceeded in heptane and chlorine-containing solvents [PhCl and (CH₂Cl)₂] as well as in toluene, and polymers were formed in good yields. The Mₜ/w values of the polymers formed were similar. On the other hand, no polymerization occurred in anisole, which is a useful solvent to prepare all-cis poly(tert-butylacetylene).

$^a$ Polymerized at 80 °C for 24 h; [M]$_0$ = 0.50 M, [TaCl$_5$] = 20 mM.

$^b$ Methanol-insoluble product.

$^c$ Determined by GPC.

Figure 1 shows the effect of temperature on the polymerization of $p$-Me$_3$SiDPA and $m$-Me$_3$SiDPA. Polymers were obtained at 30 °C and above from both monomers. The polymer yields increased with increasing temperature, and leveled off at 80 °C and above. The molecular weights of polymers hardly changed in this temperature range, being ca. 2x10$^6$ with poly($p$-Me$_3$SiDPA) and 1x10$^6$ with poly($m$-Me$_3$SiDPA). Thus, it can be said that 80 °C is favorable to obtain the present polymers in good yields.

As seen in Figure 2, the polymerization of $p$-Me$_3$SiDPA was completed within 15 min, while that of $m$-Me$_3$SiDPA in 90 min.
Thus, both polymerization are fairly quick. The fact that the polymerization of \( m \)-Me\(_3\)SiDPA is slower is probably due to the steric hindrance of the meta-SiMe\(_3\) group. The molecular weights of both polymers are independent of monomer conversion, which indicates that a stationary state is held. No changes in polymer molecular weight were observed, even though the polymerization systems were left over 24 h. This is indicative of the absence of polymer degradation after completion of polymerization which is seen in the polymerization of l-phenyl-l-propyne.\(^6\)

To clarify the influence of trimethylsilyl group on the monomer reactivity, copolymerization of \( p \)-Me\(_3\)SiDPA with DPA was attempted with TaCl\(_5\)-n-Bu\(_4\)Sn catalyst in toluene (Figure 3). \( p \)-Me\(_3\)SiDPA was consumed faster than DPA, which indicates higher relative reactivity of the former monomer. The relative...
monomer reactivity in the copolymerization of substituted acetylenes is, in general, governed by both steric and electronic effects of substituent; i.e., the monomer reactivity decreases with increasing bulkiness of substituent and/or with decreasing electron-donating ability of substituent. Since \( p-{\text{Me}}_3{\text{SiDPA}} \) should be similar in the steric effect to DPA, the observed difference in relative reactivity seems to originate from the electron-donating property of trimethylsilyl group.

**Polymer Structure**

The structure of poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)) and poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)) did not depend on the polymerization conditions. The data described below have been obtained with the polymer samples obtained with \( \text{TaCl}_5-n\text{-Bu}_4\text{Sn} \) in toluene (Table I, no. 2 and Table II, no. 2).

The elemental analysis data of poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)) and poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)) agreed well with their calculated values: Calcd for \( (C_{17}H_{18}Si)_n \): C, 81.6; H, 7.2; Si, 11.2. Found for poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)): C, 81.1; H, 8.0; Si, 10.9. Found for poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)): C, 81.1; H, 7.7; Si, 11.2.

As seen from Figure 4, the IR spectra of poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)) and poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)) do not show an absorption due to \( C=\text{C} \) stretching which was observed at 2100 cm\(^{-1} \) with the monomers. Strong absorptions characteristic of the SiC-H (1250 cm\(^{-1} \)) and Si-C (840 cm\(^{-1} \)) bonds are seen in both monomers and polymers.

\(^1\text{H} \) NMR spectra of poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)) and poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)) exhibited broad signals due to the olefinic and aromatic protons (\( \delta \) 7.5 - 5.5) and a sharp one due to the methyl protons (\( \delta \) -0.2). No unassignable signals were seen. The \(^{13}\text{C} \) NMR spectra of the polymers exhibited signals of sp\(^2\) carbons (\( \delta \) 150 - 125) and of methyl carbons (\( \delta \) 1) but showed no signals of sp carbons which were observed in both monomers at \( \delta \) 89.7 and 89.3.

It is concluded from the data described above that the present polymers possess alternating double bonds in the main chain. No information was, however, obtained regarding regiospecificity (head-to-tail and other structures) and geometric structure from IR and NMR spectra.

As seen in Figure 5, both polymers have two absorption maxima: poly(\( p-{\text{Me}}_3{\text{SiDPA}} \)) \( \lambda_{\text{max}} \) 375 nm (\( \varepsilon_{\text{max}} \) 4300 M\(^{-1}\)cm\(^{-1} \)) and 430 nm (4800); poly(\( m-{\text{Me}}_3{\text{SiDPA}} \)) 380 nm (3200) and 440
Figure 5. UV-visible spectra of poly(p-Me₃SiDPA) and poly(m-Me₃SiDPA) (measured in tetrahydrofuran; samples from Table I, no. 2 and Table II, no. 2).

nm (5100). The absorptions continue up to ca. 500 nm, which is in contrast to the absence of absorption in the visible region with the polymers from aliphatic disubstituted acetylenes. Since the present polymers appeared fluorescence, their emission spectra were measured under excitation with the light of 430 nm. Poly(p-Me₃SiDPA) showed an emission at 520 nm, while poly(m-Me₃SiDPA) at 550 nm. The emission of the former polymer was about ten times more intense than that of the latter, though the reason is not clear at present.

The X-ray diffraction data obtained with Cu Kα radiation is as follows: poly(p-Me₃SiDPA) 2θ = 6.3° (Δ2θ/2θ = 0.297), 14.3° (0.248); poly(m-Me₃SiDPA) 6.0° (0.280), 15.4° (0.461). As seen from the ratios of half-height width to diffraction angle (Δ2θ/2θ), the peaks are rather broad. Hence it can be concluded that all these polymers are amorphous. Further, the insolubility of poly(DPA) should, eventually, be due to some reasons other than crystallinity.

Figure 6. TGA curves of disubstituted acetylene polymers (in air, heating rate 10 °C/min; samples from Table I, no. 2 and Table II, no. 2).

Polymer Properties

Properties of the present polymers were hardly affected by polymerization conditions. Hence, properties were studied in detail using the same samples as employed for structural analysis.

Poly(p-Me₃SiDPA) and poly(m-Me₃SiDPA) were both yellow solids like poly(DPA). Poly(p-Me₃SiDPA) dissolved in benzene, toluene, cyclohexane, CCl₄, CHCl₃, tetrahydrofuran, anisole, diethyl ether, and triethylamine, and partly dissolved in hexane, 1,4-dioxane, (CH₂Cl)₂, and ethyl acetate. Its nonsolvents include acetone, acetonitrile, methyl benzoate, acetonitrile, N,N-dimethylformamide, dimethyl sulfoxide. Though the solubility property of poly(m-Me₃SiDPA) was similar, it was soluble in hexane. Since poly(DPA) is insoluble in any of the above-stated...
solvents, introduction of a trimethylsilyl group is obviously effective in solubilizing poly(DPA). Free-standing films could be fabricated by casting the present polymers from toluene solution.

The weight loss of poly(DPA) does not occur below 500 °C in TGA, demonstrating that it is more stable than any other substituted polyacetylenes. The temperatures at which the weight loss of poly(p-Me₃SiDPA) and poly(m-Me₃SiDPA) started in air were 420 °C and 400°C, respectively (Figure 6). These temperatures are lower than that of poly(DPA) but higher than those of most substituted polyacetylenes. Further, even when the polymers in the present study were left in air either at 120 °C for 20 h or at room temperature for one month, their molecular weights did not decrease. These results show that both of the present polymers possess high thermal stability.

The tensile properties of poly(p-Me₃SiDPA) and poly(m-Me₃SiDPA) measured at 25 °C are as follows: Poly(p-Me₃SiDPA): Young's modulus (E) = 1460 MPa, tensile strength (σ_B) = 19 MPa, elongation at break (γ_B) = 1.5%. Poly(m-Me₃SiDPA): E = 800 MPa, σ_B = 14 MPa, γ_B = 2.1%. Thus both polymers are hard and brittle, and the position of trimethylsilyl group does not greatly affect the tensile properties. The glass transition temperatures of the polymers were above 200 °C according to dynamic viscoelastic measurements.

Experimental

Materials

The monomers (new compounds) were synthesized according to the following scheme with reference to the literature methods for ethynylation and silylation.

The procedure for preparing p-Me₃SiDPA is described below as an example.

1-(p-Bromophenyl)-2-phenylacetylene: A 1-L, three-necked, round-bottomed flask was equipped with a reflux condenser, a three-way stopcock and a magnetic stirring bar, and was then flushed with dry nitrogen. Triethylamine (300 mL), (Ph₃P)₂PdCl₂ (0.56 g, 0.80 mmol), CuI (0.91 g, 4.8 mmol), Ph₃P (0.84 g, 3.2 mmol), and phenylacetylene (22.0 mL, 0.20 mol) were placed in the flask, and the mixture was stirred for 1 h. Then, p-bromiodobenzene (56.6 g, 0.20 mol) in triethylamine (300 mL) was added dropwise, and stirring was continued for an additional 1 h. After the completion of the reaction was confirmed by gas chromatography (GC), triethylamine was evaporated. Diethyl ether (ca. 400 mL) was added, and insoluble salts were removed by filtration. The solution was washed with 5% hydrochloric acid and water. The organic phase was dried over anhydrous sodium sulfate overnight, and diethyl ether was evaporated. The product was used for the next step without further purification: yield 55%, purity 99% (GC).

p-Me₃SiDPA: A 200 mL, three-necked, round-bottomed flask was equipped with a three-way stopcock, a dropping funnel, and a magnetic stirring bar. After flushed with nitrogen, a hexane solution of n-butyllithium (63 mL, 1.6 M, 0.10 mol) was placed in the flask, and the hexane (ca. 40 mL) was evaporated with an aspirator under magnetic stirring. Diethyl ether (40 mL; dried over sodium) was gradually added at -20 °C. At the same temperature, a solution of 1-(p-bromophenyl)-2-phenylacetylene (25.7 g, 0.10 mol) in diethyl ether (50 mL) was added dropwise,
and the reaction mixture was left for 30 min. At -20 °C trimethylchlorosilane (13.9 mL, 0.11 mol) was added dropwise and stirring was continued for an additional 1 h. After the completion of the reaction was confirmed by GC, ice water (20 mL) was added. The product was extracted with diethyl ether, washed with water, and dried over anhydrous sodium sulfate overnight. Diethyl ether was evaporated, and the product was purified by flush column chromatography (Nakarai Tesque Co., silica gel 60; eluent, hexane); yield 70%, purity >99% (GC), d²0 1.051.

m-Me₃SiDPA was prepared in the same way from m-bromiodobenzene. Overall yield 30%, purity >99% (GC), d²0 1.022.

Transition-metal catalysts and organometallic cocatalysts were all commercially obtained, and used without purification with care being taken not to be decomposed by moisture and/or air. Polymerization solvents were purified by the standard methods.

Polymerization

A typical procedure for the polymerization of p-Me₃SiDPA (cf. Table I, no. 2) is described below. The manipulation and reaction were carried out under dry nitrogen.

A monomer solution (2.4 mL) was prepared in a Schlenk tube by mixing p-Me₃SiDPA (0.71 mL, 0.75 g, 3.0 mmol), eicosane (0.50 mL; internal standard of GC), and toluene (1.19 mL). Another Schlenk tube was charged with TaCl₅ (35.8 mg, 0.10 mmol), n-Bu₄Sn (65.6 µL, 69.4 mg, 0.20 mmol), and toluene (3.0 mL); this catalyst solution was aged at 80 °C for 15 min. Then 2.0 mL of monomer solution was added to the catalyst solution. Polymerization was carried out at 80 °C for 24 h, and was quenched with a mixture of toluene and methanol (1 mL, volume ratio 4:1). After monomer conversion was determined by GC (Silicon DC 550, 0.5 m, 180 °C), the polymerization mixture was diluted with toluene (300 mL) and was poured into methanol (4L) under stirring to precipitate the formed polymer. The polymer was isolated by filtration and dried. The polymer yield was determined by gravimetry.

Characterization

The molecular weights of polymers were determined by gel permeation chromatography (GPC) with use of a polystyrene calibration. GPC curves were observed with a Shimadzu LC-9A liquid chromatograph [eluent, CHCl₃; columns Shodex A805, A806, and A807 polystyrene gels (Showa Denko, Co., Japan)]. Monodisperse polystyrene samples with Mₙ's of 1.0×10⁵, 3.0×10⁵, 6.5×10⁵, 1.8×10⁶, 2.0×10⁶, 3.8×10⁶, and 2.0×10⁷ were used to make a calibration curve.

IR and UV-visible spectra were recorded with Shimadzu FTIR-8100 and Shimadzu UV190 spectrophotometers, respectively. TGA was conducted with a Shimadzu 20B thermal analyzer (in air, heating rate 10 °C/min).

Chapter 2

Polymerization and Polymer Properties of Diphenylacetylenes with Bulky Silyl Groups

Abstract

Polymerization and polymer properties of diphenylacetylenes with bulky silyl groups (SiMe$_2$iPr, SiMe$_2$Bu, SiMe$_2$Ph, SiEt$_3$) at para or meta position were examined. These monomers polymerized in good yields with TaCl$_5$-cocatalysts to form high-molecular-weight polymers ($M_w >4 \times 10^5$). The polymer yields for meta-substituted monomers were lower than that for the monomer having SiMe$_3$ group, whereas no decrease was observed in the case of para-substituted monomers. Many of the polymers were soluble in common organic solvents, though the polymers with SiMe$_2$Ph and SiMe$_2$Bu groups at para position were partly insoluble. The UV-visible absorption property and thermal stability of these polymers were similar to those of poly(diphenylacetylenes) having SiMe$_3$ group obtained in Chapter 1.

Introduction

Many substituted polyacetylenes have been synthesized by using group 5 and 6 transition-metal catalysts. Among these polymers, poly[1-(trimethylsilyl)-1-propyne] [poly(TMSP)] possesses higher gas permeability than any other synthetic polymers, and its gas permeation behavior has been intensively studied. When a bulkier silyl group (e.g., SiMe$_2$-n-C$_6$H$_{13}$, SiMe$_2$Ph, SiEt$_3$) is introduced to poly(TMSP) instead of SiMe$_3$ group, i) the yield and molecular weight of polymer decrease, and ii) the gas permeability of polymer decreases. It is, however, not known whether these characteristics are seen in other polymers than poly(TMSP).

In Chapter 1, the author synthesized poly[1-phenyl-2-(trimethylsilyl)phenylacetylene] and poly[1-phenyl-2-m-(trimethylsilyl)phenylacetylene] [poly(para-1) and poly(meta-1), respectively]. These polymers were soluble in various organic solvents, and their weight-average molecular weight ($M_w$) reached over 1x10$^6$. The polymers were thermally fairly stable (the temperature at which weight loss starts is ~400 °C), and its gas permeability is about 1/4 that of poly(TMSP), being very high. It is of interest how the polymer yield, molecular weight, and properties change when the SiMe$_3$ group of poly(para-1) and poly(meta-1) is substituted by bulkier silyl groups.

In this chapter, the polymerization and polymer properties of diphenylacetylenes carrying bulky silyl groups (SiMe$_2$iPr, SiMe$_2$tBu, SiMe$_2$Ph, SiEt$_3$) by TaCl$_5$-based catalysts are described. The results are compared with those of para-1 and meta-1 to clarify the effects of bulky silyl groups.

Results and Discussion

Polymerization

Para-1 and meta-1 polymerize with TaCl$_5$-n-Bu$_4$Sn in good yields to produce high polymers whose $M_w$'s reach over 1x10$^6$. Hence, polymerization of diphenylacetylenes with bulky silyl groups was studied by using this catalyst.

Table I shows the polymerization of para-substituted diphenylacetylenes. When polymerized for 24 h, the monomers were consumed virtually quantitatively, and polymers were formed in high yields. Polymer yield decreased with increasing bulkiness of the silyl group. Soluble polymers were obtained from the monomers carrying relatively small silyl groups such as SiMe$_2$iPr and SiEt$_3$. The $M_w$'s of these polymers were ca. 160x10$^4$ being relatively close to that of para-1. On the other hand, the polymers with very bulky silyl groups like SiMe$_2$Ph

and SiMe₂Bu were partly insoluble in toluene and CHCl₃. Thus, introduction of bulky silyl groups into the para position of diphenylacetylene did not greatly change the yield and molecular weight of polymers as compared with para-1. This indicates that bulky substituents at para position hardly affects polymerization behavior, while very bulky one reduces yield and solubility of the polymer.

Meta-substituents are expected to exert a larger steric effect than do para-substituents. Thus, the polymerization of monomers having bulky meta-silyl groups was examined (Table II). Meta-1 reacts quantitatively with TaCl₅-n-Bu₄Sn to give in high yield a polymer having $M_w$ of 1x10⁶. In the polymerization of monomers with bulkier groups, on the other hand, the monomer conversions did not reach 100% after 24 h, and the polymer yields were lower than that of meta-1. Polymer yield decreased with increasing bulkiness of the silyl group. All of the produced polymers were soluble in various organic solvents, and their $M_w$'s were as high as 5x10⁵ - 10x10⁵.

As described above, the polymer yields for meta-substituted monomers were lower than that for meta-1, whereas no decrease was observed in the case of para-substituted monomers. If a substituent of a disubstituted acetylene is too bulky, the yield and molecular weight of the polymer tend to decrease. For instance, when a bulky substituent is introduced onto the silicon of MeC≡CSiMe₃, the yield and molecular weight of polymer becomes lower than those of MeC≡CSiMe₃.⁴ These facts suggest that decreases in the polymer yield and molecular weight of meta-substituted poly(diphenylacetylenes) are due to the

steric effect of meta-substituents. The differences between monomer conversion and polymer yield were due to the formation of linear oligomers with both para and meta isomers.

Cocatalyst effect on the polymerization was examined by using monomers with SiMe₂iPr group which formed soluble polymers from both para and meta isomers (para-2 and meta-2, respectively). Table III shows the effect of cocatalysts on the polymerization of para-2. No polymer was obtained with TaCl₅ alone. Polymers formed when n-Bu₄Sn, Et₃SiH, and 9BBN, which are effective in the polymerization of para-1, were used as cocatalyst. The yield and molecular weight of polymer hardly changed with these cocatalysts. On the other hand, when Ph₄Sn was used as cocatalyst, polymer yield was greatly lower than the case of other cocatalysts, though no decrease was observed for molecular weight of the polymer.

Polymerization of meta-2 was attempted by using various cocatalysts (Table IV). TaCl₅ alone was ineffective again, while use of suitable cocatalysts provided polymers. Effective cocatalysts were common in both para-2 and meta-2 and these cocatalysts gave polymers having $M_w$'s over $1 \times 10^6$ in about 60% yields.

Figure 1 shows time dependences of the polymerization with TaCl₅-n-Bu₄Sn. Under the conditions shown in Figure 1, polymerization of para-2 was completed rapidly (<15 min), whereas meta-2 was consumed completely more slowly (quantitative after 60 min). A similar difference in polymerization rate was observed between para-1 and meta-1. This is attributable to the steric effect of bulky meta-substituents. The molecular weight of polymer was independent of polymerization time, being over $1.5 \times 10^6$ and about $1.0 \times 10^6$ for

![Figure 1](image-url)
para-2 and meta-2, respectively.

**Structure and Properties of Polymers**

Polymer structure was studied by using the poly(para-2) and poly(meta-2) samples obtained in Table I. The elemental analysis values for the polymers agreed well with the ones calculated for the polymerization products; Anal Calcd for (C_{19}H_{22}Si)_n: C, 82.0; H, 7.9; Si, 10.1. Found for poly(para-2): C, 81.7; H, 8.1; Si, 10.2. Found for poly(meta-2): C, 81.5; H, 8.2; Si, 10.3.

Figure 2 shows IR spectra of poly(para-2) and poly(meta-2). In the spectra of these polymers the signals characteristic of the =C-H (3290 cm\(^{-1}\)) and =C=C (2200 cm\(^{-1}\)) bonds, which are seen in the monomer, have disappeared. The absorptions assignable to the SiC-H and Si-C bonds were observed in the spectra of both monomers and polymers. These analytical and spectral data supports that these polymers have the structure containing alternating double bonds in the main chain as shown in Figure 2.

Polymers obtained in this chapter are novel polymers with the form of yellow solid like poly(para-1) and poly(meta-1). The polymers with SiMe\(_2\)Ph and SiMe\(_2\)tBu groups, which are very bulky silyl groups, at para position were partly insoluble in common organic solvents such as toluene and CHCl\(_3\). Other polymers provided in this chapter were soluble in various organic solvents like toluene and CHCl\(_3\). Table V summarizes solubility of some silicon-containing poly(diphenylacetylenes). Which solvent dissolves a polymer depends on the kind of silyl group in the polymer.

\(^a\) ++ : soluble ± : partly insoluble.
poly(meta-1) are partly insoluble did not completely dissolve the present polymers. Further, all of the polymers having bulky silyl group were partly insoluble in anisole, whereas poly(para-1) and poly(meta-1) are soluble. These results indicate that the solubility of the present polymers is lower than that of poly(para-1) and poly(meta-1). This is probably due to the lack of flexibility of the bulky silyl groups. A self-standing film could be obtained by casting the soluble polymers.

Figure 3 shows UV-visible spectra of polymers with silyl groups at meta position. The absorption of poly(meta-1) has maxima at around 380 and 430 nm, and extends up to ~500 nm. The poly(diphenylacetylenes) carrying bulky silyl groups at meta position showed similar absorption bands and maxima, no large differences being observed with the kind of silyl group. In general, the absorption of substituted polyacetylenes tends to show a blue shift with increasing bulkiness of substituent, because bulky substituents twist the main chain to narrow the conjugation. Silyl groups at meta position, however, hardly affected the absorption. Thus, conjugation of the main chain appears to be hardly affected by the bulkiness of meta-substituent. These absorptions correspond to the yellow color of these polymers.

Generally, the thermal stability of substituted polyacetylenes increases with increasing bulkiness of substituents, because bulky substituents twist the main chain making the radical formation difficult and further preclude the reaction of the radical with oxygen. Thus, the thermal stability of poly(diphenylacetylenes) with bulky silyl groups were studied.
In the thermogravimetric analysis (TGA) of poly(diphenylacetylene) in air, no weight loss is observed up to 500 °C, indicating that the polymer possesses the highest thermal stability among substituted polyacetylenes. The temperature at which weight loss starts in air is ~400°C for both poly(para-1) and poly(meta-1), being fairly high. The polymers obtained in this chapter began to lose weight at around 350 °C. Thus, the thermal stability of these polymers is relatively high among substituted polyacetylenes, though slightly lower than those of poly(para-1) and poly(meta-1).

Experimental

Monomers (new compounds) were prepared with reference to the method for para-1 and meta-1 described in Chapter 1 using CISiR^1R^2R^3 instead of CISiMe₃. The crude product was purified by flush column chromatography (Nakarai Tesque Co., silica gel 60; eluent, hexane).

Transition metal chlorides and organometallic compounds were commercially obtained and used without further purification.

Polymerization was carried out as described in Chapter 1. Monomer conversions were determined by GC, and molecular weights of polymers were determined by gel permeation chromatography (GPC; eluent, CHCl₃, polystyrene calibration).

UV-visible spectra were recorded with a Shimadzu UV-2200 spectrophotometer. TGA was performed with a Shimadzu 20B thermal analyzer (heating rate 10 °C/min).

Chapter 3

Polymerization and Polymer Properties of 1-\[m\]-\((\text{Trimethylsilyl})\text{phenyl}\]-1-propyne

Abstract

1-\([m]\)-\((\text{Trimethylsilyl})\text{phenyl}\]-1-propyne polymerized in good yields in the presence of NbCl5- and TaCl5-based catalysts to give a new polymer (\(M_w \approx 5 \times 10^5\)). When 1-phenyl-1-propyne is polymerized with NbCl5 and TaCl5 alone, its polymer molecular weight decreases after the complete consumption of monomer. Such a phenomenon was not observed with the present monomer. The product polymer possessed the structure, \([-\text{CMe}=\text{C}(\text{C}_6\text{H}_4\text{-m-SiMe}_3)]\). The polymer was in the form of a white solid, completely soluble in common organic solvents (e.g., toluene, CHCl3), formed a self-standing film by solution casting.
**Introduction**

Silicon-containing polyacetylenes often exhibit unique properties, especially high gas permeability.\(^1,2\) For example, poly[1-(trimethylsilyl)-1-propyne] (poly(TMSP)) shows the highest gas permeability among all the synthetic polymers,\(^3\) and has recently been under intensive research.\(^4,5\) Therefore, it is of interest to introduce trimethylsilyl group into the side chain of various polyacetylenes.

Disubstituted acetylenes are known to undergo metathesis polymerization with Nb and Ta catalysts. Among them, 1-phenyl-1-propyne \(^6\) (MeC=CHPh; PhP) affords a polymer having a weight-average molecular weight \((M_w)\) over 1x10\(^5\). The polymer [poly(PhP)] is a white solid, which is soluble in many organic solvents and thermally fairly stable. It is one of the least gas-permeable polyacetylenes.

In Chapter I, the author discovered that diphenylacetylenes having SiMe\(_3\) group at meta position on one phenyl group \((\text{PhC}=\text{C}-\text{C}_6\text{H}_4-\text{m}-\text{SiMe}_3; \text{m-Me}_3\text{SiDPA})\) polymerize in good yield with TaCl\(_5\)-cocatalyst to form high polymer whose \(M_w\) reaches over 1x10\(^6\). The polymer dissolved in various organic solvents and more stable than poly(PhP). It is of interest to examine how polymerization behavior and polymer properties change if one phenyl group of \(\text{m-Me}_3\text{SiDPA}\) is replaced by methyl group.

This chapter reports on the polymerization of 1-[m-(trimethylsilyl)phenyl]-1-propyne \((\text{MeC}=\text{C}-\text{C}_6\text{H}_4-\text{m}-\text{SiMe}_3; \text{m-Me}_3\text{SiPhP})\), a silicon-containing PhP, and properties of the product polymer. The author anticipated that the \(o\)-trimethylsilyl substituted PhP would not polymerize owing to too large a steric hindrance. Hence, the meta derivative, for which an appropriate steric effect is expected, was chosen as monomer. \(\text{m-Me}_3\text{SiPhP}\) polymerized with NbCl\(_5\) to give a new, high molecular weight polymer in high yield. The polymerization behavior and polymer properties of \(\text{m-Me}_3\text{SiPhP}\) are compared with those of PhP.

**Results and Discussion**

**Polymerization**

Table I shows results for the polymerization of \(\text{m-Me}_3\text{SiPhP}\) by TaCl\(_5\)- and NbCl\(_5\)-based catalysts. When \(\text{m-Me}_3\text{SiPhP}\) was polymerized with NbCl\(_5\) alone, this monomer was completely consumed to give a methanol-insoluble polymer in high yield. The weight-average molecular weight \((M_w)\) of the polymer reached 680x10\(^3\), but the molecular weight distribution was broad. When organometallic cocatalysts, which are effective for the polymerization of PhP, were used in conjunction with NbCl\(_5\), polymers were formed in high yields as well. The polymers were, however, partly insoluble in CHCl\(_3\). The tendency that NbCl\(_5\)-cocatalyst systems produce insoluble polymers has been observed with 1-(trimethylsilyl)-1-propyne as well.\(^7\) This is probably because NbCl\(_5\) provide polymers having relatively high stereoregularity\(^8\) and further the use of a cocatalyst increases its molecular weight.

When TaCl\(_5\) alone was used as catalyst, the monomer conversion did not reach 100\%, and the polymer yield was considerably lower than that for NbCl\(_5\). Use of cocatalyst for TaCl\(_5\) was more or less effective in the increase of yield and \(M_w\) of polymer. NbCl\(_5\) alone, however, achieves a higher polymer yield than do these TaCl\(_5\)-cocatalyst systems. The differences between monomer conversion and polymer yield were due to the formation of cyclotrimers.

As described above, not only TaCl\(_5\)- but also NbCl\(_5\)-based catalysts produce polymer from \(\text{m-Me}_3\text{SiPhP}\), whereas \(\text{m-Me}_3\text{SiDPA}\) polymerizes only with TaCl\(_5\)-cocatalysts. This difference is probably due to steric effect of bulky pendant group of \(\text{m-Me}_3\text{SiDPA}\).

When PhP is polymerized with NbCl\(_5\) or TaCl\(_5\) alone, the molecular weight of the polymer formed decreases after complete consumption of monomer.\(^6\) It is interesting whether

As seen in Figure 1, the \( M_w \) of polymer increased approximately in proportion to monomer conversion. This indicates the presence of a long-lived propagating species. Such a tendency was also observed in the polymerization of 1-phenyl-1-alkynes by NbCl\(_5\) and TaCl\(_5\).

Solvent effects on the polymerization by NbCl\(_5\) were studied (Table II). High-molecular-weight polymers were obtained in

good yields not only in hydrocarbon solvents (toluene, heptane) but also in chlorine-containing solvents [CCl\(_4\), (CH\(_2\)Cl\(_2\))] and anisole.

In order to know the relative monomer reactivity in the propagation reaction, copolymerization of \( m\)-Me\(_3\)SiPhP with PhP was attempted in toluene solution at 80 °C; [\( M_1 \)] = [\( M_2 \)] = 0.25 M, [NbCl\(_5\)] = 20 mM. Both monomers reacted virtually at the same rate (relative rate, \( m\)-Me\(_3\)SiPhP:PhP = 0.9:1). Further, \( m\)-Me\(_3\)SiPhP was more reactive than 1-(\( m\)-bromophenyl)-1-propyne (\( m\)-BrPhP) in their copolymerization (relative rate, \( m\)-Me\(_3\)SiPhP:\( m\)-BrPhP = 2:1). In general, the relative monomer reactivity in copolymerization is determined by steric and electronic effects; i.e., it increases with decreasing bulkiness of substituent and with increasing electron-donating ability of substituent.\(^9,10\) Consequently, the similar reactivity of PhP and \( m\)-Me\(_3\)SiPhP are attributable to compensation of the steric and electronic effects in the latter monomer.

Structure and Properties of the Polymer

The structure and properties were studied by using the poly(\( m\)-Me\(_3\)SiPhP) obtained with NbCl\(_5\) alone in Table I.

The elemental analysis values for the polymers agreed well with the ones calculated for the polymerization products; Anal Calcd for (C\(_{12}\)H\(_{16}\)Si\(_n\)): C, 76.6; H, 8.5; Si, 14.9. Found: C, 76.9; H, 8.3; Si, 14.9.

The IR spectrum of poly(\( m\)-Me\(_3\)SiPhP) showed no signal characteristic of the C\(=\)C stretching (2200 cm\(^{-1}\)) seen in the monomer. Instead, an absorption assignable to the C\(=\)C stretching appeared at ~1580 cm\(^{-1}\) (w). Furthermore, no signals due to acetylenic carbons were observed in the \(^{13}\)C NMR spectrum of poly(\( m\)-Me\(_3\)SiPhP). These analytical and spectral data are compatible with the polymer structure of (CMe=CC\(_6\)H\(_4\)\(-m\)-SiMe\(_3\)).

Poly(\( m\)-Me\(_3\)SiPhP) is a novel polymer with the form of

![Figure 2. UV-visible spectra of poly(1-phenyl-1-propynes) (measured in cyclohexane).](image)
white solid. The solubility of the polymer is as follows: completely soluble in toluene, cyclohexane, CCl₄, CHCl₃, and anisole; partly soluble in n-hexane, diethyl ether, and tetrahydrofuran; and insoluble in (CH₂Cl)₂, 1,4-dioxane, acetone, acetonitrile, ethyl acetate, methyl benzoate, nitrobenzene, and acetonitrile. A free-standing film could be obtained by casting the polymer from toluene solution.

Figure 2 shows UV-visible spectra of poly(m-Me₃SiPhP) and poly(PhP). The absorption of poly(m-Me₃SiPhP) appears only below 400 nm; i.e., in the ultraviolet region, which corresponds to the fact that poly(m-Me₃SiPhP) is a white solid. The absorption pattern resemble that of poly(PhP), although a minor difference is seen in the 350 - 400 nm region. The absorption of poly(m-Me₃SiPhP) exists in shorter wavelength region than that of poly(m-Me₃SiDPA).

In the TGA measurement in air, poly(m-Me₃SiPhP) began to lose weight at 310 °C, whereas poly(PhP) did at 280 °C; i.e., introduction of trimethylsilyl group somewhat increased thermal stability. Even after the poly(m-Me₃SiPhP) had been heated at 120 °C for 20 h in air, no molecular-weight change was observed. Thus, poly(m-Me₃SiPhP) turns out thermally fairly stable among substituted polyacetylenes, though thermal stability of poly(m-Me₃SiPhP) is lower than that of poly(m-Me₃SiDPA) (weight loss of poly(m-Me₃SiDPA) starts at 400 °C).

Comparison with PhP

In Table III, the polymerization behavior and polymer properties of m-Me₃SiPhP are compared with those of PhP.

i) In the polymerization of PhP by NbCl₅ and TaCl₅, the molecular weight of polymer decreases after the monomer has been completely consumed. In contrast, no decrease in molecular weight occurred in the case of m-Me₃SiPhP. This is explained by an idea that the bulky trimethylsilyl group inhibits the attack of the main chain.

Table III
Comparison of Poly(m-Me₃SiPhP) with Poly(PhP)a

[a] Data from ref. 6.
a Molecular weight decrease after the polymerization by NbCl₅ and TaCl₅ is completed.
c Temperature at which weight loss starts in air.

ii) The molecular weight of poly(m-Me₃SiPhP) reached 1x10⁶, which is slightly lower than that of poly(PhP). Thus, trimethylsilyl group at meta position of PhP does not affect very much the molecular weight of the polymer formed.

iii) Though poly(m-Me₃SiPhP) obtained with NbCl₅ alone and TaCl₅-cocatalyst systems were soluble in various organic solvents, the polymers formed with NbCl₅-cocatalyst systems were insoluble. In contrast, poly(PhP) is soluble in many organic solvents irrespective of the kind of catalyst. This difference seems due to the lower flexibility of the more sterically crowded poly(m-Me₃SiPhP).

iv) The thermal stability of poly(m-Me₃SiPhP) did not greatly differ from that of poly(PhP). It is, however, noted that these polymers are thermally more stable than sterically less crowded polymers such as poly(2-alkynes).
Experimental

Materials

The monomer, \( m\text{-Me}_3\text{SiPhP} \), was prepared according to the following scheme with reference to the literature method.\(^{11}\)

\[
\begin{align*}
\text{Me-C≡C-H} + \text{I} & \xrightarrow{(\text{Ph}_3\text{P})_2\text{PdCl}_2 \text{Cuy/Ph}_3\text{P}} \text{Me-C≡C-Br} \\
n\text{-BuLi} & \xrightarrow{\text{ClSiMe}_3} \text{Me-C≡C-SiMe}_3
\end{align*}
\]

\( 1\text{-}(m\text{-Bromophenyl})\text{-1-propyne} (1) \): After flushed with dry nitrogen, a \( 500 \text{ mL} \) flask was charged with triethylamine (150 mL), \((\text{Ph}_3\text{P})_2\text{PdCl}_2 \) (0.84 g, 1.2 mmol), CuI (1.4 g, 7.2 mmol), \( \text{Ph}_3\text{P} \) (1.3 g, 4.8 mmol), and \( m\text{-bromiodobenzene} \) (15.3 mL, 0.12 mol). Then, propyne (4.5 mL, 0.24 mol) was bubbled for 5 min into the mixture at 10 \( ^\circ \text{C} \), and the mixture was stirred for 1 h at room temperature. The completion of the reaction was confirmed by gas chromatography (GC), triethylamine was evaporated. Diethyl ether (200 mL) was added, and insoluble salts were filtered off. The solution was washed with 5\% hydrochloric acid and water. The organic phase was dried over anhydrous sodium sulfate overnight, and diethyl ether was evaporated. The product (1) was distilled at reduced pressure; bp 90 - 92 \( ^\circ \text{C}/3 \text{ mmHg} \), yield 60\%, \( d^{20} 1.384 \).

\( m\text{-Me}_3\text{SiPhP} \): A 200 mL flask was flushed with dry nitrogen, and charged with a hexane solution of \( n\text{-butyllithium} \) (63 mL, 1.6 M, 0.10 mol). Part of the hexane (ca. 40 mL) was evaporated with an aspirator under magnetic stirring. After the flask was cooled at -20 \( ^\circ \text{C} \), diethyl ether (30 mL; dried over sodium) was gradually added at the same temperature, a solution of 1 (14.1 mL, 0.10 mol) in diethyl ether (10 mL) was added dropwise, and the reaction mixture was left for 30 min. At -20 \( ^\circ \text{C} \) trimethylchlorosilane (12.7 mL, 0.10 mol) was added dropwise and the mixture was allowed to stand at room temperature for 1 h. After the completion of the reaction was confirmed by GC, ice water (50 mL) was added. The product was extracted with diethyl ether, washed with water, and dried over anhydrous sodium sulfate overnight. Diethyl ether was evaporated, and the product was distilled twice at reduced pressure from calcium hydride; bp 95 \( ^\circ \text{C}/3 \text{ mmHg} \), yield 45\%, \( d^{20} 0.899 \).

Transition-metal chlorides and organometallic cocatalysts were all commercially obtained, and used without further purification. Polymerization solvents were purified by the standard methods.

Procedure

Polymerization was carried out as described in Chapter 1. The molecular weights of polymers were determined by gel permeation chromatography (GPC) with use of a polystyrene calibration. IR and UV-visible spectra were recorded with Shimadzu FTIR-8100 and Shimadzu UV 190 spectrophotometers, respectively. TGA was conducted with a Shimadzu 20B thermal analyzer (in air, heating rate 10 \( ^\circ \text{C}/\text{min} \)).

Chapter 4

Gas Permeability of Silicon-Containing Polyacetylenes

Abstract

The gas permeability of silicon-containing polyacetylenes produced in Chapters 1 - 3 and 5 - 7 was examined, and the results were compared with the data previously obtained. The $P_{O_2}$ values of poly(diphenylacetylenes) having SiMe$_3$ group at para and meta position, which were provided in Chapter 1, were $1.1 \times 10^{-7}$ cm$^3$(STP)-cm/(cm$^2$-s-cmHg) and $1.2 \times 10^{-7}$, respectively, being very high. The gas permeability of polymers having SiMe$_3$ group varied remarkably depending on the kind of substituents. Introduction of SiMe$_3$ group into hydrocarbon polyacetylenes enhanced gas permeability. If bulkier silyl group was introduced instead of SiMe$_3$ group, gas permeability of polymer decreased.
Introduction

Recently, gas-permeable membranes have been studied intensively. Such membranes are expected to be applicable to oxygen enrichment of air, artificial lungs, contact lenses, and so on. Investigation on gas-permeable membranes includes development of new membrane materials, study of permeation mechanism, fabrication of membrane modules, etc. Among them, it is very important to create polymers which show high gas permeability and permselectivity.

Various substituted polyacetylenes have been newly synthesized, and their unique properties have been clarified. One of the most salient features is high gas permeability. Though the gas permeability of substituted polyacetylenes depends on the kind of pendant groups, it is generally high. This is noteworthy particularly because these polymers are in the glass state at room temperature. Especially silicon-containing polyacetylenes tend to show high gas permeability. For instance, poly[1-(trimethylsilyl)-1-propyne] [poly(TMSP)] shows the highest gas permeability among synthetic polymers. The oxygen permeability coefficient \( P_{O_2} \) of the polymer is ca. 4\( \times 10^{-7} \) cm\(^3\) (STP)·cm/(cm\(^2\)·s·cmHg), which is 10 times that of poly(dimethylsiloxane). Its permeability mechanism and applications have recently been studied extensively.

In Chapters 1 - 3 and 5 - 7 in this thesis, the author described the synthesis of various silicon-containing polyacetylenes. From the viewpoints stated above, it is of great interest to examine the gas permeability of these polymers. Further, studies on the effect of silyl group on gas permeability will help to clarify the relationship between polymer structure and gas permeability. In this chapter, the gas permeability of silicon-containing polyacetylenes obtained in other chapters is described and the results are compared with the data previously obtained. It has been found that the polymers synthesized in Chapter 1 show very high gas permeabilities reaching ca. 1/4 those of poly(TMSP).

Results and Discussion

Silicon-containing Poly(diphenylacetylenes)

The \( P_{O_2} \) values were calculated from the increase of pressure in a downstream side when the permeate gas filled at about 1 atom in a upstream side. Figure 1 illustrates the time dependence of \( O_2 \) pressure in a downstream side of poly(diphenylacetylenes) having SiMe\(_3\) group at para position [poly\((para-1)\)]. The permeation rate was independent of the pressure of downstream side in the steady state. From the slope of this line, the \( P_{O_2} \) value of poly\((para-1)\) can be calculated.

![Figure 1. Time course of the pressure in a downstream side of poly\((para-1)\).](image-url)
The $P_{O_2}$ values of poly(diphenylacetylenes) having SiMe$_3$ group, poly(par-1) and poly(meta-1), which were obtained in Chapter 1, were $1.1 \times 10^{-7}$ cm$^3$(STP)-cm/(cm$^2$·s·cmHg) (units will be omitted below for simplicity) and $1.2 \times 10^{-7}$, respectively (Figure 2). These values are about 1/4 that of poly(TMSP) which is the most gas-permeable among all the existing polymers, and correspond to about twice that of poly(dimethyldisiloxane), which is popular as the most gas-permeable rubbery polymer. Thus, poly(par-1) and poly(meta-1) proved to be highly gas-permeable. Their separation factors between oxygen and nitrogen were about 2.0, being larger than that of poly(TMSP).

Table I shows the permeability coefficients ($P$) of silicon-containing poly(diphenylacetylenes) and poly(TMSP) to six gases. No large differences in $P$ are seen between poly(par-1) and poly(meta-1) for all the gases, which indicates that the position of SiMe$_3$ group hardly affect their gas permeability. Further, the permeability of these polymers were 1/3 - 1/6 the values of poly(TMSP) irrespective of the kind of gases. Thus, it can be said that through all these polymers gases permeate by the same mechanism which is called "dual-mode sorption model".

Figure 3 plots the $P_{O_2}$ vs $P_{O_2}/P_{N_2}$ of poly(diphenylacetylenes) with bulky substituents on silicon atom which were obtained in Chapter 2. The $P_{O_2}$ values of these polymers are in the order of $10^{-9} - 10^{-8}$, being $1/10 - 1/100$ those of poly(par-1) and poly(meta-1). $P_{O_2}/P_{N_2}$ are ca. 2.5 being larger than those of poly(par-1) and poly(meta-1). Interestingly, introduction of bulky substituents onto silicon atom reduces the gas permeability of these polymers.

Figure 4 shows the permeability coefficients of poly(diphenylacetylenes) carrying $m$-SiEt$_3$ or $m$-SiMe$_2$iPr group to six gases along with those of other polymers. It is clear that the gas permeability of substituted polyacetylenes greatly

a Gas permeability coefficients at 25 °C in the units of $1 \times 10^{-10}$ cm$^3$(STP)-cm/(cm$^2$·s·cmHg) (= barrer).
depends on the kind of substituents. However, their tendencies on the permeability to various gases resemble one another irrespective of the substituents.

Gas Permeability of Various Silicon-containing Polyacetylenes

Poly[1-[(m-(trimethylsilyl)phenyl)-1-propyne] [poly(2)] obtained in Chapter 3 is regarded as the polymer that has methyl group instead of phenyl group in poly(meta-1). The $P_{O_2}$ value of poly(2) was about 1/30 that of poly(meta-1), being small (Figure 2). Interestingly, which of phenyl and methyl is a pendant generates a great difference in the gas permeability. The $P_{O_2}$ value of poly(1-phenyl-1-propyne) is smaller than that of poly(2). This manifests that introduction of SiMe$_3$ group

Figure 3. $P_{O_2}$ vs $P_{O_2}/P_{N_2}$ of silicon-containing poly(diphenylacetylenes). (25 °C)

Figure 4. Gas permeability coefficients of polymers. (25 °C)

Figure 5. $P_{O_2}$ vs $P_{O_2}/P_{N_2}$ of substituted polyacetylenes. (25 °C)
increases gas permeability. The $P_{O_2}/P_{N_2}$ of poly(2) was ca. 3, being relatively large.

The gas permeability of ortho-substituted poly(phenylacetylenes), which belong to monosubstituted acetylene polymers, was studied (Figure 5). The $P_{O_2}$ value of poly[o-(trimethylsilyl)phenylacetylene] [poly(3)] obtained in Chapter 5 was $8 \times 10^{-9}$. Though smaller than those of poly(para-1) and poly(meta-1), this value is the highest among the ortho-substituted poly(phenylacetylenes) synthesized so far. As seen in Figure 5, the gas permeability of an ortho-substituted poly(phenylacetylene) tends to increase with increasing bulkiness of its ortho substituent. On the other hand, the $P_{O_2}$ value of poly[o-(dimethylphenylsilyl)phenylacetylene] [poly(4)] obtained in Chapter 6 was $4 \times 10^{-9}$, being much smaller than that of poly(3). This result does not necessarily correspond to the tendency described above. The $P_{O_2}/P_{N_2}$ values of poly(3) and poly(4) were as large as 3.3 and 4.0, respectively.

$P_{O_2}$ values of poly[3-(dimethyl-n-hexylsilyl)-1-hexyne] and poly[3-(dimethylphenylsilyl)-1-hexyne] obtained in Chapter 7 were $1.9 \times 10^{-9}$ and $9.5 \times 10^{-10}$, respectively. These values are slightly smaller than that of poly[3-(trimethylsilyl)-1-octyne] ($P_{O_2} = 2.7 \times 10^{-9}$).

Table II summarizes $P_{O_2}$ values of silicon-containing polyacetylenes. The following characteristics are observed in gas permeability of these polymers.

app) Among polyacetylenes having SiMe$_3$ group, the gas permeability of polymer varies remarkably depending on the kind of its substituents.

b) Gas permeability of polyacetylenes increases with increasing bulkiness of substituent. This is probably because polyacetylenes carrying bulky substituent have large space between main chains due to their bulkiness of substituent and/or the stiffness of their main chain.

iii) Introduction of SiMe$_3$ group into hydrocarbon polyacetylenes enhances gas permeability. Bulkiness and high mobility of SiMe$_3$ group can be considered for the reason.

iv) Bulky substituents on silicon atom reduce gas permeability. The reason is not clear at present, but it can be considered that by such substituents, space between main chains is filled up and/or mobility of silyl group is reduced.

In this chapter, gas permeability of various silicon-containing acetylene polymers was examined, and revealed that poly(para-1) and poly(meta-1) show very high gas permeability. Further, some relationships between polymer structure and gas permeability were discovered. The author hopes that the relationship will be clarified more and more through investigation of the gas permeability of variously substituted polyacetylenes.
Experimental

Membrane Preparation

All the membranes were obtained by casting toluene solutions of polymers (3 - 5%). The solutions were cast into a flat-bottomed Petri dish, and the solvent was removed slowly by keeping the membranes at room temperature over a few days to give homogeneous membranes with uniform thickness (~50 μm). Membrane thicknesses were measured with a micrometer.

Measurement of Gas Permeability

The gas permeation was observed on a K-315-N gas permeability apparatus (Rikaseiki Co., Japan) equipped with a MKS Baratron detector. High purity gases (He, H₂, O₂, N₂, CO₂, and CH₄; purities all >99.5%; Teisan K. K., Japan) were used. The measuring temperature was -25 °C. The downstream side of the membrane (7.0 cm³ disc) was evacuated to about 0.1 mmHg, the upstream side was filled with a gas at about 1 atm, and the increase of pressure in a downstream receiving vessel was measured. The \( P \) values were calculated from the slopes of time-pressure curves in the steady state where Fick's law held.

Synthesis and Characterization of Poly[o-(trimethylsilyl)phenyl]acetylene

Abstract

[o-(Trimethylsilyl)phenyl]acetylene quantitatively polymerized in the presence of WCl₆-Et₃SiH (1:1), W(CO)₆-hv, and MoCl₅-Et₃SiH (1:1) catalysts in toluene or CCl₄ at 30 °C to give a new polymer having weight-average molecular weight over 1×10⁶. Effects of organometallic cocatalysts, solvents, and temperature on the polymerization were studied. The polymer was in the form of a dark purple solid (λmax 542 nm), completely dissolved in common organic solvents such as toluene and CHCl₃, formed a self-standing film by solution casting, and did not lose weight below 280 °C in air, being fairly thermally stable.
Introduction

It has recently been found that not only phenylacetylene (PA) but also ortho-substituted PA's such as (o-methylphenyl)acetylene \( (o\text{-MePA}) \) and \( [o-(\text{trifluoromethyl})\text{phenyl} ]\text{acetylene} \ (o\text{-CF}_3\text{PA}) \) polymerize with W and Mo catalysts. Quite interestingly, poly\((o\text{-MePA})\) and poly\([o-(\text{trifluoromethyl})\text{phenyl} ]\text{acetylene} \ (o\text{-CF}_3\text{PA}) \) obtained have higher molecular weights than that of poly(phenylacetylene) poly(PA) irrespective of the steric hindrance due to the ortho substituents. Eventually poly\((o\text{-CF}_3\text{PA})\) provides a strong film by solution casting, whereas poly(PA) is too brittle to form a free-standing film.

So far, a number of substituted polyacetylenes have been synthesized by using transition-metal catalysts. Among these polymers are Si-containing polyacetylenes, some of which exhibit unique properties not seen in hydrocarbon polyacetylenes. For example, poly[1-(trimethylsilyl)-1-propyne] poly(TMSP)] shows extremely high gas permeability and ethanol permselectivity in the ethanol/water pervaporation. In the case of group 5 transition-metal (Nb and Ta) chlorides as catalysts, the monomer was totally consumed, but methanol-insoluble polymers were formed only in small amounts. The methanol-soluble main products showed a single peak around the molecular weight of 523 corresponding to a trimer in GPC. Further, their mass spectrum showed virtually selectively three peaks of similar magnitude at 539, 540 and 541; these peaks are assignable to the \( \text{NH}_4^+ \) adduct (541) of the trimer and to those in which one or two hydrogens have been eliminated. Therefore, the oligomeric products are thought to be the cyclotrimer [1,2,4- and 1,3,5-[tris(trimethylsilyl)phenyl]-benzenes].

Results and Discussion

Polymerization by Various Catalysts

It has been found that mixtures of WCl\(_6\) or MoCl\(_5\) (main catalyst) and Ph\(_4\)Sn (organometallic cocatalyst) are effective in the polymerization of substituted acetylenes. As seen in Table I, WCl\(_6\)-Ph\(_4\)Sn and MoCl\(_5\)-Ph\(_4\)Sn gave polymers in ca. 80% yields. The W(CO)\(_6\)-hv catalyst polymerized \( o\text{-Me}_3\text{SiPA} \) quantitatively, whereas the Mo(CO)\(_6\) counterpart was ineffective.

The \( M_w \) values of the polymers obtained with WCl\(_6\)-Ph\(_4\)Sn, W(CO)\(_6\)-hv, and MoCl\(_5\)-Ph\(_4\)Sn exceeded one million according to gel permeation chromatography (GPC; a polystyrene calibration used). It is especially noteworthy that the polymer formed with the W(CO)\(_6\)-hv catalyst had a very high molecular weight reaching \( 3 \times 10^6 \). The high molecular weight is supported by its large intrinsic viscosity (\( [\eta]\)).

In the case of group 5 transition-metal (Nb and Ta) chlorides as catalysts, the monomer was totally consumed, but methanol-insoluble polymers were formed only in small amounts. The methanol-soluble main products showed a single peak around the molecular weight of 523 corresponding to a trimer in GPC. Further, their mass spectrum showed virtually selectively three peaks of similar magnitude at 539, 540 and 541; these peaks are assignable to the \( \text{NH}_4^+ \) adduct (541) of the trimer and to those in which one or two hydrogens have been eliminated. Therefore, the oligomeric products are thought to be the cyclotrimer [1,2,4- and 1,3,5-[tris(trimethylsilyl)phenyl]-benzenes].

None of the group 8 transition-metal (Rh, Pd) catalysts and Ziegler-type catalysts produced any polymer from o-Me₃SiPA. The Rh and Fe catalysts are known to polymerize PA in high yield. Hence, it is inferred that, unlike W and Mo catalysts, these catalysts are very sensitive to the steric hindrance of the monomer. Consequently, the polymerization by W and Mo catalysts was examined in detail.

The WCl₆-Et₃SiH catalyzed polymerization of the present monomer proceeded practically quantitatively in hydrocarbons, halogenated hydrocarbons, and some oxygen-containing solvents (Table III). In contrast, nitrogen-containing compounds do not appear useful as polymerization solvents. The molecular weight of polymer appreciably varied with the kind of polymerization solvents; e.g., the $M_w$ in (CH₂Cl)₂ reached 3.7x10⁶. It is, however, not clear at present how solvents affect the polymer molecular weight.

Figure 1a illustrates the effect of temperature on the polymerization by WCl₆-Et₃SiH in toluene. When carried out at 0 °C or above, the polymerization conversion reaches 100%. The $M_w$ of polymer shows a maximum around 30 °C and clearly decreases with increasing temperature. Thus about 30 °C seems

[η] = 2.39 dL/g.
favorable to keep both yield and molecular weight of the polymer high.

The polymerization by WCl₆-Et₃SiH is completed in 1 h under the conditions shown in Figure 2a, being fairly rapid. The $M_w$ of the polymer increases with polymer yield, which suggests the presence of a long-lived propagating species. The high $M_w$ of $1.6 \times 10^6$ achieved at 1 h is maintained even if the polymerization is continued over 24 h. This indicates that polymer degradation does not occur under the polymerization conditions.

The effect of temperature on the polymerization by W(CO)₆-hv is depicted in Figure 1b. This catalyst provides the polymer at 30 °C and above, being somewhat less active than WCl₆-Et₃SiH. The high $M_w$ around $3 \times 10^6$ is achieved at relatively low temperatures such as 0 and 30 °C. As seen in Figure 2b, the

polymerization by W(CO)₆-hv reaches 100% in 1 h under the standard conditions. The $M_w$ of the polymer increases with polymer yield also in this case to reach $3\times10^6$ finally.

Polymerization by Mo Catalysts

As seen in Table IV, the polymer yield in the polymerization by MoCl₅ was affected by the kind of cocatalysts. For example, the yield was quantitative in the case of Et₃SiH, being higher than that without a cocatalyst. In contrast, Ph₃Bi exhibited an inhibiting effect. The $M_w$ of the polymer also varied to some extent with the kind of cocatalysts. The MoCl₅-Et₃SiH catalyst was employed in the following experiments for the sake of comparison with the WCl₆-Et₃SiH catalyst.

resembled those found in the polymerization by WCl₆-Et₃SiH (see Tables III and V). Namely, high polymer yields were attained in hydrocarbons, halogenated hydrocarbons, and some oxygen-containing solvents.

Regarding the polymerization temperature, the polymer yield with MoCl₅-Et₃SiH reaches 100% at 30 °C and above (Figure 1c). The $M_w$ of the polymer hardly changes in the range 30 - 90 °C. The polymerization by MoCl₅-Et₃SiH at 30 °C is completed in ca. 4 h. The $M_w$ of the polymer increases virtually in proportion to polymer yield to reach $1.1\times10^6$ at 100% yield (Figure 2c). Comparison of Figures 1a and 2a with Figures 1c and 2c leads to the conclusion that WCl₆-Et₃SiH is a more active catalyst for the present monomer than MoCl₅-Et₃SiH.

Comparison of Polymerization of PA's

PA polymerizes in high yield with W catalysts but does not polymerize in as high a yield with Mo catalysts (yields are lower than 50% even under optimal conditions).⁸³b The polymerization behavior of 1-hexyne is similar. In contrast, o-Me₃SiPA, o-CF₃PA, and tert-butylacetylene polymerize quantitatively with both W and Mo catalysts. Though the reason is not clear, it is of interest that these sterically crowded monosubstituted acetylenes achieve high yields of the polymer with Mo catalysts.

Not only o-CF₃PA but also o-Me₃SiPA give a polymer whose $M_w$ exceeded one million. The $M_w$ of poly(PA) is no more than $2\times10^5$ at the highest and that of poly(o-MePA) is in between. Thus the bulkiness of the substituent in an acetylenic monomer is a very important factor in determining the molecular weight of the polymer formed. The fact that both o-Me₃SiPA and o-CF₃PA can give high molecular weight polymers implies that the electronic effect of substituent is not a substantial factor for the high molecular weight.

In order to gain knowledge on the relative reactivity of monomers, copolymerizations of o-Me₃SiPA with PA and o-CF₃PA
were studied in toluene at 30 °C ([M$_1$]$_0$ = [M$_2$]$_0$ = 0.50 M; [WCl$_6$] = 10 mM). The relative reactivities of PA, o-Me$_3$SiPA, and o-CF$_3$PA, which were determined from their relative initial polymerization rates, were 6.2, 1.0, and 0.50, respectively. Thus, PA is most reactive among these monomers, while o-Me$_3$SiPA and o-CF$_3$PA are close to each other, irrespective of the opposite electronic effects of the ortho substituents. This fact indicates that the steric effects of the substituents affect greatly to relative monomer reactivity.

**Polymer Structure**

The structure of poly(o-Me$_3$SiPA) did not depend on the polymerization conditions. Hence, the data of the polymer sample from Table II, number 2 will be described.

The combustion analytical data of poly(o-Me$_3$SiPA) are as follows. Calcd for (C$_{11}$H$_{14}$Si)$_n$: C, 75.79; H, 8.09; Si, 16.12. Found: C, 75.78; H, 8.18; Si, 16.81. Thus the polymer possesses just the elemental composition for the polymerization product.

While strong =C-H (3290 cm$^{-1}$) and weak C=C (2100 cm$^{-1}$) absorptions are observed in the IR spectrum of the monomer, these bands disappear in the polymer (Figure 3a). Strong absorptions characteristic of the SiC-H and Si-C bonds are seen in both the monomer and the polymer.

In the $^1$H NMR spectrum of poly(o-Me$_3$SiPA) appears a broad signal due to the olefinic and aromatic protons (δ 8.0 - 4.5) and a sharp one due to the methyl protons (δ 0.0); the acetylenic proton in the monomer (δ 3.2) and any other unexpected protons are not seen (Figure 3b). The $^{13}$C NMR spectrum of polymer exhibits signals of sp$^2$ carbons in the monomer: δ 85.9 and 80.9. The $^{13}$C NMR data corresponds well to $^1$H NMR data (Figure 3c).

The IR and NMR spectra above support the idea that the polymer possesses alternating double bonds in the main chain as shown in Figure 3. The polymer should have the regular head-to-tail structure because the head-to-head structure seems
difficult to form. The geometric structure of the main chain, however, remains unsolved.

In general, the UV-visible spectrum of a substituted polyacetylenes gives some information about the conformation. Quite interestingly, poly(o-Me₃SiPA) shows a fairly large absorption maximum ($\lambda_{max}$ 6400 M⁻¹·cm⁻¹) in a very long wavelength region ($\lambda_{max}$ 542 nm) (see Figure 4). The absorption extends up to ca. 700 nm. The absorption maximum of poly(o-CF₃PA) is at 458 nm, being relatively near that of poly(o-Me₃SiPA), while that of poly(PA) is below 300 nm. In contrast, most disubstituted acetylene polymers exhibit absorptions only in the UV region. The reason why ortho substituents in poly(PA) cause a red shift is, however, not clear at present.

The X-ray diffraction data of poly(o-Me₃SiPA) obtained with Cu Kα radiation is as follows [2θ (Δ2θ/2θ); 7.6° (0.358); 15.1° (0.202). As seen from the ratios of half-height width to diffraction angle (Δ2θ/2θ > 0.20), the peaks are rather broad; this indicates that the present polymer is amorphous. The 2θ values are in a ratio of 1:2:3, being attributed to the first-, second-, and third-order diffractions, respectively, in the Bragg equation. The 2θ of 7.6 corresponds to the distance of 1.16 nm, suggesting the presence of a certain regular structure within a short range.

**Polymer Properties**

There were no discernable differences in the properties of poly(o-Me₃SiPA) with polymerization conditions. The following properties are of the polymer obtained with WCl₆-Et₃SiH (Table II, number 2).

Poly(o-Me₃SiPA) has the form of dark purple solid irrespective of the polymerization conditions. Poly(o-CF₃PA) is a dark brown solid, while poly(PA) is brown (W catalysts) or yellow (Mo catalysts). Therefore, it can be said that the ortho-substituted poly(PA)s are more deeply colored than poly(PA).

Poly(o-Me₃SiPA) dissolved in benzene, toluene, cyclohexane, CCl₄, CHCl₃, CH₂Cl₂, tetrahydrofuran, and triethylamine, while it was partly insoluble in chlorobenzene, anisole, (CH₂Cl)₂, and diethyl ether. Its nonsolvents include hexane, heptane, 1,4-dioxane, acetone, acetophenone, ethyl acetate, methyl benzoate, nitrobenzene, N,N-dimethylformamide, and acetonitrile. These solubility properties resemble those of poly(PA) and poly(o-CF₃PA).

A logarithmic plot of the intrinsic viscosity vs $M_w$ of poly(o-Me₃SiPA) is shown in Figure 5. The plot can be represented by a good linear relationship, leading to the following equation:

$$[\eta] = K M_w^a$$

(K = 2.42 x 10⁻⁵ dL/g; a = 0.764)
Figure 5. $[\eta]$ vs $\bar{M}_w$ plot for poly(o-Me₃SiPA) (the samples with polydispersity ratio of around 2.5 were used; $[\eta]$ measured in toluene at 30 °C, and $\bar{M}_w$ determined by GPC).

The exponent $a$ is 0.76 being close to that of poly(o-CF₃PA) ($a = 0.59$). These values are not so large as those for disubstituted acetylene polymers [e.g., poly(TMSP), $a = 1.04$; (-CCl=CPh-)ₙ, $a = 1.07$]. Apparently these monosubstituted acetylene polymers assume less expanded conformations in solution than do disubstituted acetylene polymers.

One can prepare a free-standing film by casting poly(o-Me₃SiPA) from toluene solution as in the case of poly(o-CF₃PA). In contrast, poly(PA) is too brittle to form a film, and the film from poly(o-MePA) is rather brittle. The film-forming properties of poly(o-Me₃SiPA) and poly(o-CF₃PA) are attributable to their high molecular weight. The author believes that the ease of preparation of poly(o-Me₃SiPA) film will greatly help find practical applications in the future.

Poly(o-Me₃SiPA) began to lose weight at about 280 °C in thermogravimetric analysis (TGA) in air (Figure 6). This temperature is higher than that for poly(PA) and is close to that for poly(o-CF₃PA). Further, the thermal stability of a polymer can be evaluated by the $\alpha$ value, which is the probability of main-chain scission on heat treatment in air at 120 °C for 20 h (defined as follows):

$$\alpha = (1/DP_n) - (1/DP_{n,0})$$

Here $DP_n$ and $DP_{n,0}$ are the number-average degrees of polymerization after and before the heat treatment. The $\alpha$ values are as follows: poly(o-Me₃SiPA), $2.0 \times 10^{-4}$; poly(o-CF₃PA), $2.5 \times 10^{-3}$; poly(PA), $1.6 \times 10^{-2}$. These ortho-substituted poly(PA)s do not suffer any molecular weight decrease of oxidation even after they have been left in air at room temperature over a few months, while poly(PA) gradually undergoes a molecular weight decrease and is oxidized to some
extent. Thus, the ortho substituents are clearly effective in enhancing the stability of the poly(PA).

The tensile properties of poly(o-Me₃SiPA) at 25 °C are as follows:8 Young's modulus, 700 MPa; tensile strength, 23 MPa; elongation at break, 4.3%. Thus it is a hard and brittle polymer. The glass transition temperature observed by dynamic viscoelasticity is above 200 °C.8 The softening point was around 360 °C.

The electrical conductivity (σ) of poly(o-Me₃SiPA) at 25 °C was 4x10⁻¹⁵ S·cm⁻¹; i.e., it is a typical insulator like poly(PA) and poly(o-CF₃PA). This is in sharp contrast to the fact that polyacetylene is a semiconductor (σ = 1x10⁻⁵ S·cm⁻¹).9 The ESR spectrum in the solid state at 25 °C showed a singlet peak with a line width of 8.1 G and a g value of 2.0034; the unpaired-electron densities (25°C) of poly(PA) and poly(o-CF₃PA) (W catalyst) are 7.9x10¹⁶ and 6.1x10¹⁷ spin/g, respectively;²b,³b that is, the value for poly(PA) is rather smaller. The high stability of these ortho-substituted poly(PA)s may be because it is difficult for oxygen to attack the main chain owing to the steric effect.

Concluding Remarks

Poly(o-Me₃SiPA), a new, high-molecular-weight polymer (Mₖ ~1x10⁶), is produced with W and Mo catalysts. Since the monomer is readily prepared through one-pot reactions from PA, it can be said that the access to the present polymer is very easy. Basic properties of the polymer have been elucidated in this chapter. Among substituted polyacetylenes, this polymer has many salient features, such as deep color, good air-stability, and film-forming property. Photoconductivity,¹⁰ and electrochromism¹¹ of poly(o-Me₃SiPA) have recently been reported elsewhere. The author hopes that novel functions will be developed further with use of the present polymer.

Experimental

Materials

The monomer was prepared according to the following scheme with some modification of the method of Brandsma:¹²

\[
\begin{align*}
\text{HC} = \text{C} & \quad 2 \text{n-BuLi} \\
& \quad \text{t-BuOK} \\
\text{LiC} = \text{C} & \quad \text{K} \\
& \quad 2 \text{ClSiMe₃} \\
\text{Me₃SiC} &= \text{Me₃Si} \\
& \quad \text{OH}^- \\
\text{HC} &= \text{C} \\
\end{align*}
\]

A 1-L, three-necked, round-bottomed flask was equipped with a reflux condenser, a three-way stopcock, a pressure-equalizing dropping funnel, and a magnetic stirring bar. The flask was flushed with dry nitrogen, and the subsequent procedures for the silylation reaction were carried out under a dry nitrogen. A hexane solution of n-butyllithium (265 mL, 1.6 M, 0.42 mol) was placed in the flask with a syringe, and the hexane (ca. 150 mL) was evaporated with an aspirator under magnetic stirring. After the flask was cooled at -20 °C, tetrahydrofuran (THF; 100 mL; dried over sodium) was gradually added. At the same temperature, a solution of PA (22 mL, 0.20 mol; distilled) in THF (50 mL) was added dropwise, and allowed to leave for 1 h. The dark red reaction mixture was cooled to -65 °C, and a solution of potassium t-butoxide (27 g, 0.24 mol) in THF (50 mL) was added dropwise, and allowed to leave for 1 h. Then chlorotrimethylsilane (53 mL, 0.42 mol; distilled) was gradually added at -50 °C and the pale yellow mixture was allowed to stand at room temperature overnight. Hexane and THF were evaporated with a rotary evaporator. A solution of potassium hydroxide (30 g) in 95%
ethanol (400 mL) was added to the white reaction mixture, and the flask was heated at 80 °C. The alkyne desilylation reaction was monitored by gas chromatography (GC) and shown to be complete within 1 h. Then, ice water (500 mL) was added. The product was extracted with diethyl ether, washed with water, and dried over anhydrous magnesium sulfate overnight. Diethyl ether was evaporated, and the product was distilled twice at reduced pressure from calcium hydride; bp 85 °C/10 mmHg (lit11a 85 °C/10 mmHg), yield 75%, purity >99% (GC), d₂⁰ 0.883.

Transition-metal chlorides and organometallic cocatalysts were all commercially obtained, and used without further purification. Polymerization solvents were purified by the standard methods.

Procedure
Polymerization was carried out as described in Chapter 1. In the case of W(CO)₆-hv and Mo(CO)₆-hv catalysts, catalyst solutions were prepared by irradiation of CCl₄ solution of W(CO)₆ or Mo(CO)₆ with a 400-W high-pressure Hg lamp from a 5-cm distance at 30 °C for 30 min.

The molecular weights of polymers were determined by gel permeation chromatography (GPC) with use of a polystyrene calibration. The GPC peaks of the polymers had a common shape, sharp on the low-molecular-weight side and gentle on the high-molecular-weight side. Since the leadings on the high-molecular-weight side were partly out of the calibration limit, the M_w and M_n values are not very accurate. Especially at a very dilute concentration of polymer sample (e.g., 0.3 g/dL), the GPC peak shifted to the high-molecular-weight side, and the leading on the high-molecular-weight side was quite pronounced. This might be due to a polymer-electrolyte-like property resulting from the doping by some impurities. This was not a case at high concentrations (1.5 - 3.0 g/dL), at which almost all the measurements were carried out.

Intrinsic viscosities ([η]) of polymers were measured in toluene at 30 °C by using a Ubbelohde-type viscometer in the concentration range 0.1 - 0.4 g/dL. The plots of η_sp/c vs. c were all linear.

Mass spectra were observed with a Shimadzu QP-1000 mass spectrometer equipped with a thermospray unit (Vestec, Model 750B). Sample solutions were prepared by dissolving samples (~0.5 mM) and ammonium acetate (0.1 M) in methanol, and the solutions (20 µL) were injected into the thermospray unit. Then samples were chemically ionized with the aid of an electron beam of 200 eV.

NMR spectra were measured on a JEOL FX90Q spectrometer. IR and UV-visible spectra were recorded with Shimadzu IR-435 and Shimadzu UV190 spectrophotometers, respectively. TGA was conducted with a Shimadzu 20B thermal analyzer (in air, heating rate 10 °C/min).

**Chapter 6**

**Polymerization and Polymer Properties of [o-(Dimethylphenylsilyl)phenyl]acetylene**

**Abstract**

[o-(Dimethylphenylsilyl)phenyl]acetylene (o-Me₂PhSiPA) polymerized with W catalysts in good yields to form high-molecular-weight polymers ($M_w >10^6$). Mo, Nb, and Ta catalysts also provided polymers, though the polymer yields and molecular weights were lower than those with WCl₆. Effects of solvents and temperature on the polymerization were studied. Living polymerization occurred when MoOCl₄-n-Bu₄Sn-ETOH catalyst was used. The produced polymer was a dark purple solid soluble in various organic solvents. UV-visible spectrum and thermal stability of the polymer was similar to those of poly[o-(trimethylsilyl)phenylacetylene].
Introduction

Polymerization of various ortho-substituted phenylacetylene has been recently studied; e.g., o-methylphenylacetylene,\(^1\) o-(trifluoromethyl)phenylacetylene,\(^2,3\) o-(trimethylsilyl)phenylacetylene \((o-\text{Me}_3\text{SiPA}),\(^4\) and derivatives of \(o-\text{Me}_3\text{SiPA}\.\(^5\) These monomers showed the following characteristics: i) they polymerize in good yields by W and Mo catalysts to form linear, soluble polymers; ii) the molecular weight of the produced polymers increases with increasing steric crowding in the monomer irrespective of the electronic effect of the substituents; iii) monomers with bulky ortho substituents undergo living polymerization in the presence of Mo-based three-component catalysts; iv) the absorption of polymer in the UV-visible spectrum shows a red shift as the ortho-substituent becomes bulkier; v) the gas permeability of the polymers tends to increase with increasing bulkiness of the ortho substituent.

\(o-\text{Me}_3\text{SiPA}\) has the bulkiest substituent among the ortho-substituted phenylacetylenes whose polymerization has been examined. The above-stated characteristics are evidently seen with \(o-\text{Me}_3\text{SiPA}\.\(^4\)

It is of interest to examine whether such characteristics are strengthened or not if an even bulkier substituent is introduced into the ortho position of phenylacetylene. As one of such monomers the author chose \([o-(\text{dimethylphenylsilyl})\text{phenyl}]\text{acetylene} \((o-\text{Me}_2\text{PhSiPA}).\) This chapter reports on the polymerization and polymer properties of \(o-\text{Me}_2\text{PhSiPA}.\) The results obtained are compared with those of \(o-\text{Me}_3\text{SiPA}\.\)

Results and Discussion

Polymerization

Table I shows results of the polymerization by various catalysts. The WCl\(_6\)-E\(_3\)SiH \((1:1)\) catalyst, which is known to be very effective in the polymerization of \(o-\text{Me}_3\text{SiPA},\) produced a methanol-insoluble polymer in the highest yield. The methanol-soluble products were mixture of linear oligomers and cyclotrimers. The product polymer, poly\((o-\text{Me}_2\text{PhSiPA}),\) was soluble in toluene and CHCl\(_3\), whose \(\bar{M}_w\) reached 73\(\times\)10\(^4\). The W(CO)\(_6\)-hv catalyst also gave a polymer in high yield. The \(\bar{M}_w\) of the polymer exceeded 1\(\times\)10\(^6\), being higher than that with WCl\(_6\)-Et\(_3\)SiH. When MoCl\(_5\)-Et\(_3\)SiH was used both yield and molecular weight of polymer decreased as compared with the WCl\(_6\) counterpart. In general, both WCl\(_6\)- and MoCl\(_5\)-based catalysts are effective in the polymerization of phenylacetylene and its ortho-substituted derivatives, though the former is more active.

than the latter.\textsuperscript{6} This tendency holds also with \(\sigma\)-Me\(_2\)PhSiPA.

\(\text{NbCl}_5\text{Et}_3\text{SiH}\), a catalyst based on a group 5 transition metal, also provided poly(\(\sigma\)-Me\(_2\)PhSiPA) with \(M_w\) of ca. 20x10\(^4\), though the polymer yield remained low. The TaCl\(_5\)Et\(_3\)SiH catalyst also showed some activity like \(\text{NbCl}_5\text{Et}_3\text{SiH}\). It is known that group 5 transition-metal chlorides selectively cyclotrimerize most monosubstituted acetylenes. Monomers with a very bulky substituent, however, produce polymers with such catalysts [e.g., HC=CC\(_6\text{H}_4\))-\(\sigma\)-Me\(_2\)-p-\(\text{Bu}\),\textsuperscript{7} HC=CC\(_6\text{H}_4\)-o-Ph]. Thus, the above results manifest that the steric effect of the ortho-substituent of \(\sigma\)-Me\(_2\)PhSiPA is considerably large.

Effects of solvents on the polymerization were studied by using \(\text{WCl}_6\text{Et}_3\text{SiH}\) which achieved the highest polymer yield (Table II). Polymers were obtained in good yields not only in toluene but also in other solvents like hexane, (CH\(_2\text{Cl}\))\(_2\) and anisole. It has been noted that the polymerization by TaCl\(_5\) does not occur in anisole, while that by \(\text{WCl}_6\), MoCl\(_5\), and NbCl\(_5\) does take place in anisole. The present result corresponds to the precidents. Though the \(M_w\) values varied depending on the

\(c\) Determined by GPC.

Figure 1 depicts the effect of temperature on the polymerization by \(\text{WCl}_6\text{Et}_3\text{SiH}\). The polymer yield is 56% at 0 °C (monomer conversion is 91%), and increases to about 80% at 30 °C and above. The \(M_w\) value, which is \(-\text{1x}10^6\) at 0°C, decreases with rising polymerization temperature. These results indicate that temperatures around 30 °C are optimal to obtain a high-molecular-weight polymer in good yield.

**Living Polymerization**

\(\sigma\)-Me\(_2\)SiPA undergoes living polymerization in the presence of MoOCl\(_4\)-n-Bu\(_4\)Sn-EOH (1:1:1) catalyst to form a polymer with narrow molecular weight distribution (MWD; \(M_w/M_n \sim 1.1\)).\textsuperscript{8} Thus, living polymerization of \(\sigma\)-Me\(_2\)PhSiPA by this catalyst was attempted. As seen in Figure 2, the number-average molecular weight of polymer (\(M_n\)) increased in direct proportion to
monomer conversion. The polymerization rate was rather slow; i.e., even when \( o\)-Me\(_2\)PhSiPA was polymerized for 6 h, the monomer conversion was 85% and not quantitative. The MWD remained narrow (\( M_\text{w}/M_\text{n} < 1.1 \)) throughout the polymerization. These results manifest that \( o\)-Me\(_2\)PhSiPA polymerizes in a living manner with the MoOCl\(_4\)-based three-component catalyst like \( o\)-Me\(_3\)SiPA. Thus, it is obvious that the \( o\)-dimethylphenylsilyl group, a very bulky ortho substituent, of phenylacetylene does not necessarily lower the livingness of its polymerization.

**Polymer Properties**

Since it was found that properties of poly\((o\)-Me\(_2\)PhSiPA\) do not depend on the polymerization conditions, those of the poly\((o\)-Me\(_2\)PhSiPA\) obtained by WCl\(_6\)-Et\(_3\)SiH in toluene at 30 °C will be described.

Poly\((o\)-Me\(_2\)PhSiPA\) is a dark purple solid. It is completely soluble in aromatic hydrocarbons (toluene, benzene), chlorinated hydrocarbons (CCl\(_4\), CHCl\(_3\), CH\(_2\)Cl\(_2\)), and tetrahydrofuran. Its nonsolvents include aliphatic hydrocarbons (cyclohexane, hexane), ethers (anisole, diethyl ether, 1,4-dioxane), ketones (acetone, acetonaphone), esters (ethyl acetate, methyl benzoate), and triethylamine. Poly\((o\)-Me\(_3\)SiPA\) dissolves in cyclohexane and triethylamine, which indicates that the present polymer is less soluble than poly\((o\)-Me\(_3\)SiPA\). A free-standing film could be prepared by casting poly\((o\)-Me\(_2\)PhSiPA\) from toluene solution.

The absorption maximum of poly\((o\)-Me\(_2\)PhSiPA\) lie at 532 nm (\( \lambda_{\text{max}} \) 5700 M\(^{-1}\).cm\(^{-1}\)) and the absorption extends up to ca. 700 nm (Figure 3). The absorption of \( o\)-substituted poly-(phenylacetylene) shows red shifts with increasing bulkiness of substituent; e.g., \( \lambda_{\text{max}} \) 466 nm \( (o\)-CH\(_3\))\(^1\), 542 nm \( (o\)-SiMe\(_3\))\(^4\).
Absorption of poly(o-Me_2PhSiPA) is, however, similar in wavelength to that of poly(o-Me_3SiPA).

Poly(o-Me_3SiPA) begins to lose weight in thermogravimetric analysis (TGA) in air at 280 °C, having relatively high thermal stability among substituted acetylene polymers. The weight loss of poly(o-Me_2PhSiPA) started at 275 °C, indicating that thermal stability of poly(o-Me_2PhSiPA) is similar to that of poly(o-Me_3SiPA).

**Experimental**

o-Me_2PhSiPA (new compound) was prepared with reference to the method for o-Me_3SiPA described in Chapter 5 using ClSiMe_2Ph instead of ClSiMe_3. The crude product was purified by flush column chromatography (Nakarai Tesque Co., silica gel 60; eluent, hexane). Overall yield 30%, purity >95% (by GC).

Transition metal chlorides and organometallic compounds were commercially obtained and used without further purification.

Polymerization was carried out as described in Chapter 5. Monomer conversions were determined by GC, and molecular weights of polymers were determined by gel permeation chromatography (GPC; eluent, CHCl_3, polystyrene calibration).

UV-visible spectra were recorded with a Shimadzu UV-2200 spectrophotometer. TGA was performed with a Shimadzu 20B thermal analyzer (heating rate 10 °C/min).

Polymerization and Polymer Properties of 3-Silyl-1-hexynes

Abstract

3-(Dimethyl-n-hexylsilyl)-1-hexyne and 3-(dimethyl-phenylsilyl)-1-hexyne [HC=CH(SiMe2R)-n-C3H7; R = n-C6H13, Ph; new compounds] formed polymers in excellent yields in the presence of Mo and W catalysts. The highest weight- and number-average molecular weights ($M_w$ and $M_n$) of poly[3-(dimethyl-n-hexylsilyl)-1-hexyne] were ca. $4 \times 10^5$ and $2 \times 10^5$, respectively (MoCl5-Ph3Sb as catalyst), while the highest $M_w$ and $M_n$ of the corresponding phenyl-substituted polymer were ca. $2 \times 10^5$ and $8 \times 10^4$ (WCl6-Ph3Sb). Both of the present polymers were yellow solids, whose structure could be represented as [-CH=CH(CHSiMe2R-n-C3H7)]n. They dissolved in many common organic solvents and could be cast from solution into films. Mechanical, thermal, and some other properties of the polymers are discussed.
**Introduction**

Recently, many polymers have been synthesized from substituted acetylenes by use of transition metal catalysts. Among the polymers, Si-containing polyacetylenes often exhibit unique properties and functions (e.g., high gas permeability); thus, their synthesis is an intriguing subject. One of the simplest Si-containing acetylenes is (trimethylsilyl)acetylene. This monomer, however, usually produces a polymer partly insoluble in common organic solvents, and the molecular weight of its soluble fraction is no more than ca. $1 \times 10^4$. Monomers in which one of the methyl groups in (trimethylsilyl)acetylene is replaced by other groups such as $n$-hexyl and phenyl also provide only polymers with similar molecular weights.

In a previous study, 3-(trimethylsilyl)-1-alkynes [HC=CC(SiMe$_3$)-n-alkyl, 1] were employed as another type of Si-containing monosubstituted acetylenes, and their polymerization was studied. 3-(Trimethylsilyl)-1-butyne (1a) and -1-hexyne (1b) polymerized with Mo and W catalysts, but the polymers did not completely dissolve in any solvents. In contrast, 3-(trimethylsilyl)-1-octyne (1c) and -1-decyne (1d), homologues with longer alkyl chains, gave polymers which were totally soluble in solvents such as toluene and chloroform and had high molecular weights up to $5 \times 10^5$. Though the insolubility of polymers of 1a and 1b is assumed to be due to rather poor flexibility of the side chain, it is not necessarily evident.

From the previous investigations, it has been observed that in the polymerization of substituted acetylenes, molecular weight of the produced polymer increased with increasing bulkiness of substituent. Thus, it can be expected that molecular weight becomes higher than the case of 1c if one of the methyl groups on the silicon atom in 1b is replaced by bulkier groups. Further, it is of interest to study the effect of bulkier silyl group on polymer properties. Especially, soluble polymers might be obtained from these monomers.

This chapter reports on the polymerization of 3-(dimethyl-$n$-hexylsilyl)-1-hexyne (2) and 3-(dimethylphenylsilyl)-1-hexyne (3), both of which are novel compounds belonging to the monomer group of 3-silyl-1-hexynes.

**Results and Discussion**

**Polymerization of 3-(Dimethyl-$n$-hexylsilyl)-1-hexyne (2)**

The polymerization of this monomer was first examined with various catalysts (Table 1). Under the polymerization conditions shown in Table 1, the monomer was completely consumed in the presence of the Mo, W, and Nb catalysts, except for the case of Ph$_3$Bi as cocatalyst. The major products with the Mo, W, and Nb catalysts were methanol-insoluble poly[3-(dimethyl-$n$-hexylsilyl)-1-hexyne]s (poly(2)), whose yields were in the range ca. 40-100%. In contrast, the polymer yields with Ta catalysts were zero. It is very interesting that 3-silyl-1-alkynes [1c, 1d, and the present monomers] polymerize in the presence of Nb catalysts when it is taken into account that most monosubstituted acetylenes are selectively cyclotrimerized with...

$^a$ Polymerized in toluene at 0 °C (Mo, W) or 30 °C (Nb, Ta) for 24 h; $[M]_0 = 0.50$ M, $[cat] = [cocat] = 10$ mM.

$^b$ Methanol-insoluble product.

$^c$ Determined by GPC.

$^d$ Polymerized in CCl$_4$ at 30 °C.

Nb and Ta catalysts.$^7$ The methanol-soluble product in the polymerizations was a mixture of linear oligomers and cyclotrimers according to gel permeation chromatography (GPC) as well as IR and NMR spectra.

The weight- and number-average molecular weights ($M_w$ and $M_n$) of poly(2) obtained with MoCl$_5$-Ph$_3$Sb (Table I, no. 2) were $41 \times 10^4$ and $20 \times 10^4$, respectively, being the highest among the values in the table.$^6$ It is noted that not only polymer yield but also molecular weight is rather low with MoCl$_5$-Ph$_3$Bi, though Ph$_3$Bi is a Group 5 organometallic compound like Ph$_3$Sb. The molecular weight of polymer was usually lower when W and Nb catalysts were used instead of Mo catalysts.

As compared with MoCl$_5$ alone, catalysts composed of MoCl$_5$ and an organometallic cocatalyst more or less changed the polymerization rate, polymer yield, and molecular weight. For instance, the polymerization by MoCl$_5$ alone was finished after several hours, whereas the one by MoCl$_5$-Ph$_3$Sb was completed within 1 h. It is obvious in Table I that use of Ph$_3$Sb as cocatalyst increases the polymer molecular weight. As seen in Table I, the Mo(CO)$_6$-hv catalyst is as effective as MoCl$_5$-based catalysts. Similar tendencies are observed also with WCl$_6$-cocatalyst and W(CO)$_6$-hv systems.

Solvent effect on the polymerization was studied by using MoCl$_5$-Ph$_3$Sb which proved to be one of the most useful catalysts (Table II). Although the monomer was quantitatively consumed not only in toluene but also in anisole and halogen-containing solvents, the polymer yield in toluene was the highest (>90%). The $M_w$ of poly(2) became the highest in toluene among the solvents examined.

Figure 1 shows the effect of temperature on the polymerization by MoCl$_5$-Ph$_3$Sb in toluene. The monomer conversion at 0 °C and above was quantitative under the conditions in Figure 1. The polymer yield was about 90% in the range 0 - 60 °C, while it was lower at -20 °C. The $M_w$ of poly(2)

a Polymerized at 0 °C for 24 h; [M]₀ = 0.50 M, [MoCl₅] = [Ph₃Sb] = 10 mM.

b Methanol-insoluble product.
c Determined by GPC.

Figure 1. Effects of temperature on the polymerization of 3-(dimethyl-n-hexylsilyl)-1-hexyne by MoCl₅-Ph₃Sb (in toluene, 24 h, [M]₀ = 0.50 M, [MoCl₅] = [Ph₃Sb] = 10 mM).

Figure 2. Time courses of the polymerization of 3-(dimethyl-n-hexylsilyl)-1-hexyne by MoCl₅-Ph₃Sb (in toluene, 0 °C, [M]₀ = 0.50 M, [MoCl₅] = [Ph₃Sb] = 10 mM).

exhibited a maximum around 0 °C. Therefore, 0 °C is suitable to obtain a high molecular weight polymer in high yield.

When this polymerization was carried out with MoCl₅-Ph₃Sb in toluene at 0 °C, all of monomer 2 was virtually consumed after 1 h, and at that point the yield of methanol-insoluble polymer reached about 90% (Figure 2). Then the $M_w$ of the poly(2) was as high as ca. $4 \times 10^5$; even though the polymerization was continued over 24 h, the molecular weight did not change, indicating that no polymer degradation occurred.

Polymerization of 3-(Dimethylphenylsilyl)-1-hexyne (3)
The polymerization of 3 was examined with various catalysts (Table III). In the case of this monomer, W catalysts usually achieved higher $M_w$'s than did the corresponding Mo catalysts. Eventually, WCl₅-Ph₃Sb provided virtually

a Polymerized in toluene at 0 °C (Mo, W) or 30 °C (Nb, Ta) for 24 h; [M]₀ = 0.50 M, [cat] = [cocat] = 10 mM.
b Methanol-insoluble product.
c Determined by GPC.
d Polymerized in CCl₄ at 30 °C.

It proves that the effect of cocatalyst is different depending on the kinds of catalyst (WCl₆ and MoCl₅); e.g., Ph₃Sb is very effective when combined with WCl₆, while it is not as effective with MoCl₅. As in the case of monomer 2, Nb catalysts were useful to some extent in effecting polymerization, whereas Ta catalysts hardly produced poly(3).

Though the polymerization of monomer 3 by WCl₆-Ph₃Sb proceeded in solvents other than toluene, the polymer yield considerably decreased, and the $M_w$ reduced to about 1/10 the value with toluene (Table IV). As shown in Figure 3, the polymerization by WCl₆-Ph₃Sb in toluene exhibited the highest values for both yield and $M_w$ of polymer at 0 °C; the $M_w$ decreased sharply with increasing temperature. Thus, the selection of an appropriate temperature is very important in this case.

polymerization. The polymerization of monomer 3 by WCl₆-Ph₃Sb was not completed within a few hours (Figure 4), being slower than the polymerization of monomer 2 by MoCl₅-Ph₃Sb. The $M_w$ of polymer increased with polymerization time to reach ca. $2 \times 10^5$ after 24 h. The increase of $M_w$ with increasing polymer yield suggests the presence of long-lived propagating species.

Comparison of Polymerization of Various 3-Silyl-1-alkynes

When monomers 2 and 3 are compared with each other concerning their polymerization behavior, the following can be pointed out on the basis of the above-stated results: (i) 2 is more reactive than 3 according to the dependences on temperature and time; (ii) the highest $M_w$'s differ (poly(2) $4 \times 10^4$; poly(3) $2 \times 10^4$); (iii) the kinds of catalysts which attain the highest $M_w$'s differ (MoCl₅-Ph₃Sb for 2; WCl₆-Ph₃Sb for 3).

In a previous paper,⁵ polymers partly insoluble in toluene were obtained in the polymerization of monomer 1b by MoCl₅.

a Polymerized in toluene at 0 °C for 24 h; [M]₀ = 0.50 M, [cat] = [cocat] = 10 mM; the monomer conversions were all 100%.

b Methanol-insoluble product.
and WCl₆ in toluene at 30 °C. For the sake of comparison, a few polymerizations of this monomer were carried out under the same conditions as in Table I and III. As seen in Table V, methanol-insoluble poly[3-(trimethylsilyl)-1-hexyne] [poly(1b)] was obtained in high yields. The yields of poly(1b) were somewhat higher with Mo catalysts than with the W counterparts. The effect of Ph₃Sb as cocatalyst on the polymer yield was negligible. All of the poly(1b) in Table V was only partly soluble in common solvents such as toluene and CHCl₃.

In the polymerization of monomer 1c, Mo catalysts produce poly[3-(trimethylsilyl)-1-octyne] [poly(1c)] with higher molecular weight in better yields than W catalysts do; especially, MoCl₅-Et₃SiH affords poly(1c) in ca. 90% yield with $M_w$ of 45 x 10⁴. These results resemble those for monomer 2. The fact that monomer 3 behaves somewhat differently seems due to the steric effect of the phenyl group.

It was confirmed in the present study that 3-silyl-1-hexynes produce polymer with higher molecular weight than do silylacetylene. It is presumed that the silyl group directly bonded to the acetylenic carbon is more or less reactive to participate in the chain transfer in the polymerization of silylacetylenes.

**Polymer Structure**

Unless otherwise specified, the structure and properties of polymers were investigated with use of sample 2 of Table I for poly(2), sample 10 of Table III for poly(3), and sample 2 of Table V for poly(1b).

The elemental analysis values of the present polymers agreed fairly well with the theoretical values calculated for the polymerization products: Anal. Poly(2) Calcd for (C₁₄H₂₈Si)₌; C, 74.91; H, 12.57. Found: C, 74.78; H, 12.79. Poly(3) Calcd for (C₁₄H₂₀Si)₉; C, 77.71; H, 9.32. Found: C, 76.69; H, 9.28.

Figure 5 gives IR spectra of polymers. The absorption band at 1580 cm⁻¹ in every polymer is assignable to C=C stretching. Though the absorption is not strong, it appears clearly unlike the case of the polymers from symmetrically disubstituted acetylenes. In these polymers are seen no signals characteristic of the C=C (≈ 2150 cm⁻¹) and ≡C-H (≈ 3300 cm⁻¹) bonds which appear in their monomers. Absorptions indicating the presence of Si atom are seen at 1250 cm⁻¹ (Si-C-H deformation) and in the range 800 - 700 cm⁻¹ (Si-C stretching).
The $^{13}$C NMR spectrum of poly(2) shows two peaks δ 143 and 128 due to olefinic carbons (Figure 6). In the spectrum of poly(3), the peaks of olefinic carbons overlap with those of phenyl carbons. In both polymers, the signals of alkyl carbons appear in the range δ 40 - 0, among which the methyl carbons bonded to Si are just at δ 0. Acetylenic carbons which should appear between δ 90 and 65 are not seen in these polymers.

The data of UV-visible spectra of the polymers measured in cyclohexane are as follows: poly(2) $\lambda_{\text{max}}$ 351 nm ($\varepsilon$ 3900) (absorption $\leq$486 nm); poly(3) $\lambda_{\text{max}}$ 350 nm ($\varepsilon$ 2800) (absorption $\leq$480 nm). Corresponding to the UV-visible spectra, both polymers were yellow solids.

It will be reasonable to conclude from the above data that the present polymers possess the alternating double bond structure, [-CH=C(CHSiMe$_2$R-n-C$_3$H$_7$)-]$_n$, which assumes appreciably twisted conformations. These data and conclusions are analogous with those for poly(1c) reported in a previous paper.

**Polymer Properties**

Whereas poly(1b) is partly insoluble in toluene and chloroform, the present polymers completely dissolve in these solvents. The flexible and/or bulky groups of n-hexyl and phenyl are able to interact with the solvent effectively, which should have made these polymers soluble, unlike poly(1b). At the same time, the idea that the insolubility of poly(1b) stems from crosslinking can be denied. As seen in Table VI, there is a considerable difference in the kind of solvents used for poly(2) and poly(3). For instance, poly(2) dissolves in hexane, an alkane,

but does not dissolve in ethyl acetate, fairly polar solvent, whereas the opposite is the case with poly(3).

When the mechanical properties of poly(2) and poly(3) are compared (Table VII), the former polymer has a lower Young's modulus, a smaller tensile strength, and a larger elongation at break. This is explainable in terms of the difference in the nature of substituents n-hexyl and phenyl. It turns out that poly(1c) is close to poly(3) in mechanical properties, rather than to poly(2). Roughly talking, all these polymers are somewhat soft and ductile among various substituted polyacetylenes owing to the presence of relatively long alkyl groups.8

Most of the substituted polyacetylenes possess high glass transition temperatures ($T_g$) around 200 °C.8 Among substituted polyacetylenes, poly(2) has a relatively low $T_g$ (Table VII), which is attributable to the presence of a flexible n-hexyl group. In contrast, poly(3), which does not have such a long alkyl group, exhibits a high $T_g$. By a similar reason, the softening points of these polymers are pretty different from each other. The $T_g$ and softening point of poly(1c) are again closer to those of poly(3) than to those of poly(2).

The weight loss of the present two polymers in the thermogravimetric analysis (TGA) in air starts in the vicinity of 200 °C (Table VII). This means that the thermal stability of these polymers is medium and not very high among various substituted polyacetylenes.9 The presence of an allylic proton in these polymers seems responsible for this. When these polymers are heat-treated in air at 120 °C for 20 h, they suffer moderate decreases of molecular weight (Table VII) among substituted polyacetylenes.9 This also leads to a conclusion similar to that for TGA. The $M_w/M_n$ ratio after the heat treatment is relatively close to two, which indicates that virtually only random degradation of the polymer takes place, and cross-linking is negligible.

The electrical conductivities of poly(2) and poly(3)
measured in the dark at 25 °C with dc current are \(9 \times 10^{-18}\) and \(7 \times 10^{-18}\) S·cm\(^{-1}\), respectively. These values are indicative of typical insulators. The unpaired electrons in the present polymers were undetectable by the electron spin resonance measured at 25 °C in bulk. Therefore, their unpaired electron levels should be lower than \(1 \times 10^{15}\) spin·g\(^{-1}\). These electrical and magnetic data suggest that the double bonds in the present polymers are conjugated only to a limit extent. The insulating and nonparamagnetic properties are common in many of the polyacetylenes with bulky substituents.\(^{1a}\)

**Experimental**

Monomers 2 and 3 were prepared with reference to the literature methods for synthesizing 3-(trimethylsilyl)-1-alkynes\(^{5,10}\) according to the following scheme:

\[
\begin{align*}
\text{HC}=&\text{C}n\text{C}_4\text{H}_9 & \text{HC}=&\text{C}·\text{CH}_2\text{C}_3\text{H}_7 \\
\text{ClSiMe}_2\text{R} & \xrightarrow{2\text{n-BuLi}} & \text{HC}=&\text{C}·\text{CH}_2\text{C}_3\text{H}_7\text{Li} & (R = n-\text{C}_8\text{H}_{13}\text{(2)}) \\
\text{H}_2\text{O} & \xrightarrow{\text{SiMe}_2\text{R}} & \text{HC}=&\text{C}·\text{C}_n\text{H}_3\text{C}_7 & \text{Ph (3)}
\end{align*}
\]

Dimethyl-\(n\)-hexylsilyl chloride, a starting compound, was prepared according to ref 2b. Monomer 2 was prepared as follows: Under dry nitrogen, a flask was charged with a hexane solution (263 mL) of \(n\)-BuLi (0.42 mol) and part of the hexane (ca. 100 mL) was removed by evaporation with an aspirator. The concentrated solution of \(n\)-BuLi was diluted slowly with diethyl ether (200 mL; dried over sodium) at -50 °C. 1-Hexyne (23.0 mL, 0.20 mol) was added dropwise while keeping the flask at -30 °C; after the addition, the mixture was gradually heated and refluxed at ca. 35 °C for 2 h. At -10 °C, dimethylphenylsilyl chloride (Shin-Etsu Silicon, Japan; 33.1 mL, 0.20 mol) was added dropwise; then the mixture was stirred at ambient temperature for 2 h. Water was added at 0 °C, and the reaction was worked up similarly to the case of monomer 2. Yield 45%; bp 95 °C/5 mmHg; purity 95% (GC). IR (neat) 3300 (s, \(\nu_{\text{C-H}}\)), 3050 (m), 2950 (s), 2860 (m), 2100 (m, \(\nu_{\text{C=C}}\)), 1430 (m), 1250 (s, \(\delta_{\text{Si-C-H}}\)), 1105 (s), 820 (s, \(\nu_{\text{Si-C}}\)), 790 (m), 725 (m), 700 (m), 630 (m) cm\(^{-1}\). \(^{13}\)C NMR (CDCl\(_3\)) \(\delta\) 136.8 (C\(_{\text{sp2-Si}}\)), 133.9 (2C\(_{\text{p}}\)), 129.2 (2C\(_{\text{p}}\)), 127.7 (2C\(_{\text{m}}\)), 86.2 (C\(_{\text{p}}\)), 69.0 (C\(_1\)), 31.2 (C\(_4\)), 22.4 (C\(_5\)), 19.0 (C\(_3\)), 13.5 (C\(_6\)), -4.4 (Me-Si), -5.2 (Me\(^{11}\)Si).
Transition metal chlorides and organometallic compounds were commercially obtained and used without further purification. Polymerization and analyses were carried out in the same manner as described in Chapter 5.

References and Notes

6. The yields and molecular weights ($\bar{M}_w$ and $\bar{M}_n$) of polymers shown in the tables of the present study were reproducible within experimental errors of ca. 10%.

Polymerization and Polymer Properties of [2,5-Bis(trifluoromethyl)phenyl]acetylene

Abstract

[2,5-Bis(trifluoromethyl)phenyl]acetylene [BTFPA; \( \text{HC} = \text{C} \text{C}_6\text{H}_3 \text{-2,5-(CF}_3\text{)}_2 \)] polymerized with W, Mo, and Nb catalysts to produce methanol-insoluble polymers in high yields. The poly(BTFPA) produced by the W(CO)_6-based catalysts at 30 °C was soluble in \( p-(\text{CF}_3\text{)}_2\text{C}_6\text{H}_4 \), and had relatively high molecular weight (\( \eta \)) = 0.352 dL/g in \( p-(\text{CF}_3\text{)}_2\text{C}_6\text{H}_4 \). The main chain of the polymer was composed of alternating double bonds, and the polymer was a dark brown solid. The temperature at which the weight loss of the polymer started in air was higher than 300 °C. The polymerization behavior and polymer properties for BTFPA are compared with those for phenylacetylene and \( o-\text{(trifluoromethyl)phenyl]acetylene} \).
Introduction

Fluorine-containing polymers often show unique properties such as high thermal stability and resistance to chemicals.\(^1\) Rather few fluorine-containing polyacetylenes, however, have been known, whose recent examples include;\(^2\) (CH=C-n-C\(_4\)F\(_9\)),\(^3\) (CMe=CC\(_6\)F\(_5\)),\(^4\) poly[1-ethynyl-5-(trifluoromethyl)naphthalene].\(^4\) 

\(o\)-(Trifluoromethyl)phenylacetylene (\(o\)-CF\(_3\)PA) produced a soluble polymer whose weight-average molecular weight (\(\langle M_w \rangle\)) reaches 1 \(\times\) 10\(^6\).\(^5,6\) This polymer is film-forming unlike poly(phenylacetylene), and possesses thermal stability higher than that of poly(phenylacetylene). In the polymerization of substituted acetylenes by group 5 and 6 transition-metal catalysts, a general tendency has been observed that when the substituent of monomer possesses suitable bulkiness, a high-molecular-weight polymer is formed.\(^7\) Further, it is expected that a polymer with high fluorine content shows unique properties. From these viewpoints, it is of interest to study the polymerization of phenylacetylenes having more than one CF\(_3\) groups.

\end{array}
\]

\[
\text{BTFPA}
\]

In this chapter, the author investigated the polymerization and polymer properties of [2,5-bis(trifluoromethyl)phenyl]acetylene (BTFPA). This monomer is featured by steric crowding and high fluorine content. The results obtained are compared with those for \(o\)-CF\(_3\)PA.

Results and Discussion

Polymerization

Table I summarizes results for the polymerization of BTFPA by group 5 and 6 transition-metal catalysts. When W catalysts such as WCl\(_6\)-Ph\(_4\)Sn and W(CO)\(_6\)-hv were used, methanol-insoluble polymers were obtained virtually quantitatively. Among Mo catalysts, MoCl\(_5\)-Ph\(_4\)Sn produced a polymer in high yield, while no polymer was obtained with Mo(CO)\(_6\)-based catalyst. Interestingly, NbCl\(_5\)-Ph\(_4\)Sn also produced polymer in good yield, and methanol-soluble part was cyclotrimers. It has been known that NbCl\(_5\)-based catalysts selectively give cyclotrimers from most monosubstituted acetylenes except those with bulky substituents.\(^7\) \(o\)-CF\(_3\)PA provides only cyclotrimers in

behavior was observed between the polymerization in (CH₂Cl)₂ (nonsolvent of the polymer) and that in fluorine-containing solvents (relatively good solvents of the polymer). On the other hand, no polymer was obtained in oxygen-containing solvents such as anisole and acetophenone.

To compare the reactivity of the present monomer with that of o-CF₃PA, copolymerization of BTFPA with o-CF₃PA was examined (Figure 2). o-CF₃PA reacted faster than BTFPA. In general, a monomer with less bulky substituent is more reactive in the copolymerization of substituted acetylenes. Further, the ¹³C NMR chemical shifts of acetylenic carbons of these monomers were similar to each other. Therefore, it can be said that the meta CF₃ group of BTFPA affected the copolymerization sterically to reduce its reactivity.

The presence of NbCl₅. Hence, it can be concluded that the meta CF₃ group of the present monomer sterically plays an important role in polymerization. The intrinsic viscosity of the polymer obtained with W(CO)₆-hv at 30 °C was 0.352 dL/g in p-(CF₃)₂C₆H₄ suggesting that the polymer has a relatively high molecular weight.

Figure 1 shows temperature dependences of the polymerizations by WCl₆·Ph₄Sn and W(CO)₆-hv both of which produced polymer in good yields. The polymer yield with these catalysts remained low at a low temperature of -30 °C. In contrast, polymers were obtained virtually quantitatively at 30 °C and above. Though the W(CO)₆-based catalyst is generally less active than the WCl₆-based catalyst, these catalysts show similar activities for the present monomer.

Table II shows solvent effects on the polymerization of BTFPA by WCl₆·Ph₄Sn. Polymers were obtained in good yields not only in toluene but also in chlorine- and fluorine-containing solvents. No substantial difference in the polymerization
Figure 2. Copolymerization of $\text{HC} \equiv \text{C}-\text{C}_6\text{H}_3-2,5-(\text{CF}_3)_2$ with $\text{HC} \equiv \text{C}-\text{C}_6\text{H}_4-o-\text{CF}_3$ by WCl$_6$-Ph$_4$Sn (in toluene, 30 °C, $[\text{M}_1]_0 = [\text{M}_2]_0 = 0.50$ M, $[\text{WCl}_6] = [\text{Ph}_4\text{Sn}] = 20$ mM).

Structure and Properties of Polymer

The elemental composition of the polymer agreed well with the one for the addition polymerization products (Anal Calcd for $(\text{C}_9\text{H}_4\text{F}_6)_n$: C, 50.45; H, 1.67; F, 47.88. Found: C, 51.03; H, 1.43; F, 47.54).

Figure 3 exhibits the IR spectra of BTFPA monomer and its polymer. The spectrum of the polymer shows no absorptions characteristic of the =C-H (3300 cm$^{-1}$) and =C=C (2200 cm$^{-1}$) bonds which are seen in the spectrum of the monomer. Instead, an absorption due to the C=C bond is observed at 1620 cm$^{-1}$ in the polymer. The strong complicated band at 1350 - 1000 cm$^{-1}$ are assignable to C-F stretching. Absorptions due to a 1,2,5-trisubstituted benzene are also seen at 780 and 700 cm$^{-1}$. The analytical and IR spectral data support that the main chain of the polymer is composed of alternating double bonds as shown in Figure 3.

Figure 3. IR spectra of $\text{HC} \equiv \text{C}-\text{C}_6\text{H}_3-2,5-(\text{CF}_3)_2$ and its polymer (KBr pellet).

Figure 4. UV-visible spectra of poly(phenylacetylenes) (measured in tetrahydrofuran, but poly(BTFPA) in $p-(\text{CF}_3)_2\text{C}_6\text{H}_4$).
The poly(BTFPA) obtained in the present study was a dark brown solid. The polymer produced with the W(CO)₆-based catalyst was completely soluble in p-(CF₃)₂C₆H₄, though polymers obtained in other conditions were partly insoluble in this solvent. Regarding other solvents, poly(BTFPA) was partly soluble in tetrahydrofuran, C₆F₆, and CCl₂FCClF₂ (soluble part 30 - 70%), virtually insoluble in hexane, CHCl₃, and (CH₂Cl)₂. The proportion of soluble part varied to some extent with the polymerization conditions. The polymer obtained with W(CO)₆ in CCl₄ at 30 °C was the most soluble (the soluble part in C₆F₆ was about 70%). Poly(o-CF₃PA) is totally soluble in common organic solvents such as toluene and CHCl₃, but insoluble in some polyfluorinated hydrocarbons such as C₆F₆ and p-(CF₃)₂C₆H₄. The difference in solubility in these two polymers should originate from differences in the fluorine-content and the stiffness of the polymer chain.

Figure 4 shows the UV-visible spectrum of poly(BTFPA). An absorption maximum of the polymer lies at about 420 nm, and no absorption is seen above 680 nm. This absorption band is almost similar to that of poly(o-CF₃PA), and is in a region of fairly long wavelength as compared with that of poly(phenylacetylene). Generally, the absorption maximum of an ortho-substituted phenylacetylene polymer shifts to longer wavelength with increasing bulkiness of the substituent. Poly(BTFPA) also exhibits this tendency.

Figure 5 shows results of thermogravimetric analysis (TGA) of the present and analogous polymers. Poly(phenylacetylene) begins to lose weight at a relatively low temperature of 200 °C. In contrast, the temperatures at which weight loss starts are 300 °C and 320 °C with poly(o-CF₃PA) and poly(BTFPA), respectively. These polymers are thermally more stable than poly(phenylacetylene), because bulky CF₃ groups twist the main chain making the radical formation difficult and further preclude the reaction of the radical with oxygen.

Experimental

The monomer, BTFPA, was prepared according to the following procedure reported by Okuhara et al.:
Overall yield 55%, bp 65 °C/30 mmHg, d²⁰ 1.310

Transition metal chlorides and organometallic compounds were commercially obtained and used without further purification.

Polymerization and analyses were carried out in the same manner as described in Chapter 5.

Polymerization and Polymer Properties of (Perfluoro-n-alkyl)acetylenes

Abstract

(Perfluoro-n-alkyl)acetylenes (HC=CR; Rf = n-C6H13, n-C4H9) polymerized with the WC6-Ph4Sn catalyst to produce methanol-insoluble polymers in good yields. The intrinsic viscosities of the polymers (in C6F6) were ca. 0.05 dL/g, being relatively small. No large difference was observed between the polymerization in toluene (heterogeneous) and that in C6F6 (homogeneous). The main chain of the polymers was composed of alternating double bonds. These polymers were white solids soluble in C6F6. The temperatures at which the weight loss of the polymers started were higher than 200 °C, which indicates improved thermal stability as compared with the corresponding poly(1-alkynes).
Introduction

Fluorine-containing polymers such as poly(tetrafluoroethylene) are known to show unique properties such as water and oil repellency, thermal stability, and resistance to chemicals. Thus far several polymers have been obtained from fluorine-containing aromatic acetylenes by using groups 5 and 6 transition-metal catalysts; e.g., poly(1-pentafluorophenyl-1-alkynes) (insol.),\(^1\) poly[\(\sigma\)-(trifluoromethyl)phenylacetylene] (high MW),\(^2,3\) poly[1-ethynyl-5-(trifluoromethyl)naphthalene] (medium MW).\(^4\)

On the other hand, the polymerization of fluorine-containing aliphatic acetylenes is virtually restricted to a few examples as follows: polymerization of HC=CCF\(_3\) with PdCl\(_2\)/DMF or n-BuLi\(^5\) and of CF\(_3\)C=CCF\(_3\) with \(\bigoplus\)KF,\(^6\) both of which only produce insoluble polymers.

1-Alkynes polymerized with WCl\(_6\) catalysts in good yield.\(^7\) The polymer which is soluble in organic solvents such as toluene is not thermally stable. It is expected that thermal stability is improved if perfluoroalkyl group is introduced instead of alkyl group.

This chapter deals with the polymerization of \((\text{perfluoro-}n\text{-alkyl})\text{acetylenes} with relatively long perfluoroalkyl groups (HC=CR\(_f\); \(R_f = n\text{-C}_{6}F_{13}, n\text{-C}_{4}F_{9}\)). These monomers polymerized with WCl\(_6\)-Ph\(_4\)Sn catalyst to produce new polymers which are white, totally soluble in C\(_6\)F\(_6\), and more stable than the corresponding poly(1-alkynes).

Results and Discussion

Polymerization of \((\text{Perfluoro-}n\text{-alkyl})\text{acetylenes}

Table I lists results for the polymerization of \((\text{perfluoro-}n\text{-hexyl})\text{acetylene}. When polymerization was carried out with

d Polymerized in CCl\(_4\); [cat] = 10 mM.

WCl\(_6\)-Ph\(_4\)Sn as catalyst in toluene solution, a methanol-insoluble polymer was obtained in ca. 50% yield. The methanol-soluble product was a mixture of linear oligomers and cyclotrimers. Apart from toluene as solvent, polymers could be obtained in CCl\(_4\) and various fluorine-containing solvents. The polymer yields in these solvents, however, were 15 - 30%, being lower than that in toluene. The intrinsic viscosities of the polymers produced in toluene and CCl\(_2\)FCClF\(_2\) were in the range of ca. 0.05 - 0.08 dL/g, indicating that the molecular weight of the polymers are rather low like poly(1-alkynes). The intrinsic viscosities of the polymers did not greatly change with the kind of polymerization solvents. It is noted that no substantial difference in the yield and molecular weight of polymer is
observable between toluene or CCl₄ (non-solvents of the polymer) and fluorine-containing solvents (relatively good solvents of the polymer). When WCl₆ alone was used as catalyst, or when n-Bu₄Sn, Ph₃SiH, Et₃SiH, Ph₃Bi, and Ph₃Sb were added as cocatalysts to WCl₆, no methanol-insoluble polymer was obtained. No reaction occurred with W(CO)₆-hv or MoCl₅-Ph₄Sn. Ziegler-catalysts such as Fe(acac)₃-3Et₃Al and Ti(O-n-Bu)₄-4Et₃Al produced only methanol-soluble oligomers. Thus it has turned out that the effective catalyst for this monomer is restricted to WCl₆-Ph₄Sn.

Table II gives data for the polymerization of (perfluoro-n-hexyl)acetylene, a homologue with a shorter perfluoroalkyl group. When the WCl₆-Ph₄Sn catalyst was used in conjunction with the solvents shown in the table, monomer was completely consumed and methanol-insoluble polymers were obtained in high yields around 80%. The intrinsic viscosities of the produced polymers were 0.05 - 0.06 dL/g, no large difference being observed irrespective of the kind of solvents.

Copolymerization of (perfluoro-n-hexyl)acetylene with 1-octyne by WCl₆-Ph₄Sn catalyst was attempted (polymerization conditions: in toluene, 30 °C, 24 h, [M]₀ = [M₂]₀ = 0.25 M, [WCl₆] = [Ph₄Sn] = 20 mM). Consequently, 1-octyne was completely converted within 1 h, while (perfluoro-n-hexyl)acetylene was not consumed at all even after 24 h. Further, 1-(perfluoro-n-hexyl)-1-pentyne (n-C₆F₄C≡C-n-C₃H₇) was not consumed at all in the polymerization by MoCl₅-n-Bu₄Sn catalysts (polymerization conditions: in toluene, 30 °C, 24 h, [M]₀ = 0.25 M, [WCl₆] = [Ph₄Sn] = 20 mM); it gives striking contrast to the fact that internal alkynes polymerize well in the presence of MoCl₅- and/or WCl₆-based catalysts. These results suggest that the coordinating ability of fluorine-containing acetylenes are inferior to that of the corresponding aliphatic acetylenes.

Structure and Properties of Polymers

The structure and properties of the present polymers did not essentially differ with polymerization conditions. Hence, the data for the polymer samples prepared with WCl₆-Ph₄Sn in toluene will be described below.

The elemental analysis values for the polymers agreed fairly well with the values calculated for the addition polymerization products (e.g., Anal Calcd for (C₈H₁₇F₁₃)ₙ: C, 27.91; H, 0.30; F, 71.80. Found: C, 28.30; H, 0.45; F, 70.21).

Figure 1 exhibits the IR spectra of (perfluoro-n-hexyl)acetylene and its polymer. The spectrum of the polymer shows no absorptions characteristic of the ≡C-H and ≡C=C bonds which are clearly seen in the spectrum of the monomer. Instead, an absorption due to the ≡C≡C bond is observed at 1620 cm⁻¹ in the polymer. The strong complicated band at 1350 - 1000 cm⁻¹ is due to C-F stretching. These analytical and IR spectral data
Figure 1. IR spectra of HC≡C-n-C6F13 and its polymer (KBr pellet).

Figure 2. TGA curves of poly[(perfluoro-n-alkyl)acetylenes] (in air, heating rate 10 °C/min).

their weight loss starts below 150 °C in TGA.9 In contrast, the temperatures at which these fluorine-containing polymers started to lose weight were fairly high (220 - 230 °C), indicating enhanced thermal stability. It can be said that the present polymers have fairly good thermal stability among monosubstituted acetylene polymers because of bulkiness of the side chain and/or lack of H atom in the perfluoroalkyl groups.9

As shown in Figure 3, the UV-visible spectra of poly[(perfluoro-n-alkyl)acetylenes] exhibited an absorption maximum at around 250 - 300 nm, and no absorption above 340 nm. These absorption bands are in a shorter wavelength region than are those of the corresponding poly(1-alkynes). This can be explained in terms that the bulky perfluoroalkyl groups twist the polymer backbone to reduce the extent of conjugation. These spectra correspond well with the fact that the present polymers
are white, whereas the poly(1-alkynes) are yellow to orange. The absorption of the present polymers weakened with increasing length of perfluoroalkyl group.

The electrical conductivities of poly[(perfluoro-n-alkyl)acetylenes] were in the order of $10^{-17}$ S·cm$^{-1}$, indicative of typical electrical insulators.

**Experimental**

Monomers were offered by Japan Halon Co., Ltd.: HC≡C-n-C$_6$F$_{13}$ bp 96 °C/760 mmHg, purity [gas chromatography (GC)] 99%; HC≡C-n-C$_4$F$_9$ bp 47 °C/760 mmHg, purity (GC) 98%.

Transition metal chlorides and organometallic compounds were commercially obtained and used without further purification.

**Polymerization and analyses** were carried out in the same manner as described in Chapter 5.

Acknowledgments

This thesis presents the studies which the author has carried out at the Department of Polymer Chemistry, Kyoto University, during the years from 1986 to 1991.

The author would like to express his sincere gratitude to Professor Toshinobu Higashimura for his continuous guidance, helpful suggestions, and encouragement throughout the course of this work.

Grateful acknowledgment is due to Associate Professor Toshio Masuda for his constant guidance, valuable suggestions, and encouragement.

The author wishes to express his gratitude to Dr. Mitsuo Sawamoto for his suggestions and discussions.

The author is indebted to Dr. Takeji Hashimoto and Mr. Kenji Saijo (Department of Polymer Chemistry, Kyoto University) for the measurement of X-ray diffraction, and to Dr. Takashi Kawamura (Gifu University) for the measurement of ESR.

Greatful thanks are due to Mr. Toshiyuki Hamano for his kind guidance in experimental techniques and discussions, and also to Messrs. Tatsuya Oshita and Shin-ichiro Katahira for their collaborations. Appreciations are also due to all of his colleagues in the Higashimura Laboratory for their invaluable suggestions.

Finally, the author heartily wishes to thank his parents, Toyoji Tsuchihara and Hiroko Tsuchihara, for their care and encouragement.

March, 1992
