Asymmetric travelling waves in a square duct

Shinya Okino and Masato Nagata[†]

Department of Aeronautics and Astronautics, Graduate School of Engineering, Kyoto University,
Kyoto, 606-8501, Japan

(Received 11 March 2011; revised 3 October 2011; accepted 17 October 2011;
first published online 6 January 2012)

Two types of asymmetric solutions are found numerically in square-duct flow. They emerge through a symmetry-breaking bifurcation from the mirror-symmetric solutions discovered by Okino *et al.* (*J. Fluid Mech.*, vol. 657, 2010, pp. 413–429). One of them is characterized by a pair of streamwise vortices and a low-speed streak localized near one of the sidewalls and retains the shift-and-reflect symmetry. The bifurcation nature as well as the flow structure of the solution show striking resemblance to those of the asymmetric solution in pipe flow found by Pringle & Kerswell (*Phys. Rev. Lett.*, vol. 99, 2007, A074502), despite the geometrical difference between their cross-sections. The solution seems to be embedded in the edge state of square-duct flow identified by Biau & Bottaro (*Phil. Trans. R. Soc. Lond. A*, vol. 367, 2009, pp. 529–544). The other solution deviates slightly from the mirror-symmetric solution from which it bifurcates: the shift-and-rotate symmetry is retained but the mirror symmetry is broken.

Key words: bifurcation, nonlinear instability, transition to turbulence

1. Introduction

Incompressible viscous flow through a straight duct with a square cross-section driven by a constant pressure gradient is believed to be linearly stable as in the case of pipe flow (Davey & Drazin 1969; Tatsumi & Yoshimura 1990). Therefore, there exists no solution which bifurcates from the laminar state and the transition to early stages of turbulence is abruptly caused by a finite-amplitude disturbance. The transitional regime for these flows is considered to be represented by the trajectory in the phase space wandering around unstable nonlinear solutions, called ECS (exact coherent structures), such as steady states, travelling waves and periodic solutions, which are disconnected from the laminar state. Hence, identifying ECS is important in understanding the turbulent dynamics and the laminar–turbulent transition from a dynamical-systems point of view. In pipe flow a number of ECS have been computed (Faisst & Eckhardt 2003; Wedin & Kerswell 2004; Pringle & Kerswell 2007; Duguet, Pringle & Kerswell 2008a; Duguet, Willis & Kerswell 2008b; Pringle, Duguet & Kerswell 2009). In contrast, only three travelling waves that are ECS have been reported so far in square-duct flow (Wedin, Bottaro & Nagata 2009; Okino *et al.* 2010; Uhlmann, Kawahara & Pinelli 2010). This is partially because solutions in a pipe are easily generalized to larger families by the rotational symmetry with an arbitrary angle,

[†] Email address for correspondence: nagata@kuaero.kyoto-u.ac.jp

whereas those in a square duct only have 90° rotational symmetry. The nonlinear travelling wave in a square duct in Wedin *et al.* (2009) was obtained for the first time by the self-sustaining process approach (Wedin *et al.* 2008), which was originally introduced by Waleffe (1997) for plane Couette flow. The solution has a four-vortex mean flow. However, the sense of the rotation of the vortices is opposite to the pattern observed at the transitional Reynolds number by a direct numerical simulations (DNS) study (Uhlmann *et al.* 2007). The mean flow of the solution in Uhlmann *et al.* (2010) shows a diagonally symmetric eight-vortex pattern. It is consistent with Prandtl's secondary flow of the second kind in square-duct turbulence. In Okino *et al.* (2010), a nonlinear analysis of internally heated square-duct flow is performed, extending the linear stability analysis of Uhlmann & Nagata (2006). The isothermal solution is reached by a continuation approach in the parameter space. The dominant vortex structure of the mean flow of the solution resembles that of marginally turbulent flow (Uhlmann *et al.* 2007).

Investigation by DNS is another approach to understanding the transitional turbulent dynamics. Recently, much attention has been paid to the so-called edge state, which is the invariant set on the boundary between the laminar and turbulent states in phase space (Itano & Toh 2001; Schneider, Eckhardt & Yorke 2007; Duguet *et al.* 2008b; Schneider *et al.* 2008; Biau & Bottaro 2009; Mellibovsky & Meseguer 2009; Schneider & Eckhardt 2009). The trajectory, which starts with an initial condition near the laminar–turbulent boundary, transiently approaches the edge state before the flow relaminarizes or evolves into turbulence.

For more thorough accounts of studies on square-duct flow readers should refer to the introduction of Okino *et al.* (2010).

In this paper, we are concerned with the mathematical, rather than physical, aspects of the transition to early stages of turbulence in a square-duct flow. We investigate the linear stability of the travelling wave solution found in Okino *et al.* (2010). Perturbations are split into four different symmetry groups. After having identified the linear critical points, we calculate bifurcating nonlinear solutions. We shall show evidence that one of the nonlinear solutions obtained matches with the edge state adequately.

2. Linear stability analysis of the mirror-symmetric solution

We take the Cartesian coordinates (x_*, y_*, z_*) with the origin at the centre of the duct, where the x_* -axis is directed along the duct and the y_* - and z_* -axes are parallel to the sides of the square cross-section. The subscript $*$ denotes dimensional variables. A pressure gradient is applied along the duct. The motion of the fluid in the duct is governed by the continuity equation, the Navier–Stokes equation and the no-slip boundary condition. The governing equations are non-dimensionalized by the length scale b_* , the time scale b_*^2/ν_* and the velocity scale ν_*/b_* , where b_* is half the side of the square cross-section of the duct and ν_* is the kinematic viscosity of the fluid. The flow is characterized by the Reynolds number, $Re = U_{c*}b_*/\nu_*$, where U_{c*} is the centreline velocity of the laminar flow. The pressure drop has a proportionality with the centreline velocity: $\chi = 3.3935Re$, where χ is the non-dimensional pressure drop (Tatsumi & Yoshimura 1990).

Periodicity in the x -direction with wavenumber α is imposed. We assume a travelling wave as a nonlinear solution: the velocity $\mathbf{u} = (u, v, w)$ is represented by $\mathbf{u}(x - ct, y, z)$, where c is the phase velocity.

Asymmetric travelling waves in a square duct

59

The travelling wave found in Okino *et al.* (2010), which we refer to as ONWB hereafter, is invariant under the following transformations: shift-and-reflect,

$$\mathbf{S} : (u, v, w)(\xi, y, z) \rightarrow (u, -v, w)(\xi + \pi/\alpha, -y, z), \quad (2.1)$$

and mirror-reflect,

$$\mathbf{Z} : (u, v, w)(\xi, y, z) \rightarrow (u, v, -w)(\xi, y, -z), \quad (2.2)$$

where $\xi = x - ct$. The combination of $\mathbf{S}$ and $\mathbf{Z}$ leads to the shift-and-rotate,

$$\mathbf{\Omega} : (u, v, w)(\xi, y, z) \rightarrow (u, -v, -w)(\xi + \pi/\alpha, -y, -z). \quad (2.3)$$

We follow the method of Okino *et al.* (2010) to investigate the linear stability of solution ONWB. Based on Floquet theory, the velocity perturbations, $\tilde{\mathbf{u}}$, are expanded as a Fourier series in the streamwise direction as follows:

$$\tilde{\mathbf{u}}(x, y, z, t) = \sum_{l=-L}^L \tilde{\mathbf{u}}_l(y, z) \exp[i l \alpha (x - ct) + \sigma t]. \quad (2.4)$$

The Fourier spectra, $\tilde{\mathbf{u}}_l = (\tilde{u}_l, \tilde{v}_l, \tilde{w}_l)$, are expanded by modified Chebyshev polynomials, which satisfy the no-slip boundary conditions. The stream function $\tilde{\varphi}_0$ represents the cross-sectional flow, introduced to take the place of the mean parts, $\tilde{v}_0$ and $\tilde{w}_0 : \tilde{v}_0 = \partial_z \tilde{\varphi}_0$ and $\tilde{w}_0 = -\partial_y \tilde{\varphi}_0$. The discretization of the equations is done by the Galerkin method. Examining the governing equations for the perturbations (see (4.4), (4.5), (4.8) and (4.9) of Okino *et al.* 2010), we find that the following four symmetry groups for $\tilde{v}_l, \tilde{w}_l, \tilde{u}_0$ and $\tilde{\varphi}_0$ are admissible:

symmetry IA :

$$\tilde{v}_l \left\{ \begin{matrix} (l^+; e, e) \\ (l^{++}; o, e) \end{matrix} \right\}, \tilde{w}_l \left\{ \begin{matrix} (l^+; o, o) \\ (l^{++}; e, o) \end{matrix} \right\}, \tilde{u}_0(e, e), \tilde{\varphi}_0(o, o), \quad (2.5)$$

symmetry IB:

$$\tilde{v}_l \left\{ \begin{matrix} (l^+; e, o) \\ (l^{++}; o, o) \end{matrix} \right\}, \tilde{w}_l \left\{ \begin{matrix} (l^+; o, e) \\ (l^{++}; e, e) \end{matrix} \right\}, \tilde{u}_0(e, o), \tilde{\varphi}_0(o, e), \quad (2.6)$$

symmetry IC :

$$\tilde{v}_l \left\{ \begin{matrix} (l^+; o, e) \\ (l^{++}; e, e) \end{matrix} \right\}, \tilde{w}_l \left\{ \begin{matrix} (l^+; e, o) \\ (l^{++}; o, o) \end{matrix} \right\}, \tilde{u}_0(o, e), \tilde{\varphi}_0(e, o), \quad (2.7)$$

symmetry ID:

$$\tilde{v}_l \left\{ \begin{matrix} (l^+; o, o) \\ (l^{++}; e, o) \end{matrix} \right\}, \tilde{w}_l \left\{ \begin{matrix} (l^+; e, e) \\ (l^{++}; o, e) \end{matrix} \right\}, \tilde{u}_0(o, o), \tilde{\varphi}_0(e, e). \quad (2.8)$$

Here, l^+ and l^{++} denote the odd and even Fourier mode in (2.4), respectively. The notation e or o indicates that the variable is an even or odd function with respect to the y - or z -coordinate. Symmetry IA is the same as the one that the solution ONWB possesses: the perturbations are invariant under the transformations $\mathbf{S}$ and $\mathbf{Z}$ (and therefore also under $\mathbf{\Omega}$). It is immediately verified that symmetries IB, IC and ID individually have symmetry $\mathbf{S}$, $\mathbf{Z}$ and $\mathbf{\Omega}$, respectively. The stability analysis for symmetry IA has already been reported in Okino *et al.* (2010).

FIGURE 1. The real part of the growth rate, $\text{Re}(\sigma)$, of the perturbations with symmetry IB on the (a) lower and (b) upper branches of ONWB with $\alpha = 1.14$. Solid and dashed curves indicate that the growth rates are real and complex conjugate, respectively.

FIGURE 2. Same as figure 1, but for the perturbations with (a) symmetry IC and (b) symmetry ID on the upper branch.

Figure 1 shows the real part of the growth rate σ of the perturbations with symmetry IB on the lower and upper branches of ONWB. We choose $\alpha = 1.14$ for which the bulk Reynolds number, Re_b , takes its minimum. Re_b can be calculated by integrating the mean velocity over the cross-section (see (3.9) of Okino *et al.* 2010). As shown in figure 1(a), the largest growth rate has a complex-conjugate eigenvalue at $Re = 827.5$ (the saddle-node of ONWB). It decreases as the Reynolds number increases. The neutral point is found at $Re \sim 1450$. The second largest eigenvalue, which starts as a complex-conjugate pair, splits into two real eigenvalues at $Re \sim 1000$, and the larger one crosses zero at $Re \sim 1080$ (filled circle). No other neutral points are found on the lower branch within the parameter range of our investigation ($Re \leq 3000$) when perturbations with symmetries IA, IC and ID are considered.

Figure 1(b) shows that the second eigenmode with symmetry IB on the upper branch, associated with a complex eigenvalue at the saddle-node of ONWB, crosses zero at $Re \sim 880$ and splits into two real modes at $Re \sim 1450$. After the split the lower branch mode becomes neutral when $Re \sim 1480$ (open circle). As shown in the figure 12(b) of Okino *et al.* (2010), all the neutral modes with symmetry IA on the upper branch are associated with a complex-conjugate pair. The growth rate of the perturbations with symmetry IC on the upper branch is shown in figure 2(a). The leading eigenvalue appears as a complex-conjugate pair. They cross zero three times

FIGURE 3. (a) The bulk Reynolds number versus the Reynolds number and (b) the phase velocity versus the Reynolds number for $\alpha = 1.14$. Dotted curve: ONWB. Solid curve: the S -symmetric solution. Dashed curve: the Ω -symmetric solution. Thin dotted line: the laminar state, $Re_b = 0.47704Re$. The circles and the inverted triangle show the bifurcation points.

before $Re \sim 1300$ and take positive growth rates thereafter. Only one neutral mode associated with a real eigenvalue is found for $Re \sim 1990$ (open diamond). Figure 2(b) shows that the upper branch solution is stable to perturbations with symmetry ID before five unstable eigenmodes (one real and two complex conjugate pairs) appear almost together near $Re = 1400$.

3. Bifurcation of asymmetric travelling wave solutions

We are interested only in nonlinear solutions that bifurcate from ONWB at the neutral points with real eigenvalues, as seen in figures 1 and 2. Using the eigenfunction at the neutral points as an initial guess for the Newton–Raphson method, we obtain two bifurcating solutions from ONWB with $\alpha = 1.14$. The bulk Reynolds numbers, Re_b , and phase velocities, c , for these solutions as well as ONWB are plotted against the Reynolds number in figure 3. Also, the skin friction, λ , versus the bulk Reynolds number is shown in figure 4. Here, we define the skin friction, $\lambda = 4\chi/Re_b^2$ (χ is the non-dimensional pressure drop in the streamwise direction), as a measure of the nonlinearity. The dotted curve in figures 3 and 4 indicates the ONWB branch. A new solution, which results from the instability due to symmetry IB and retains only symmetry S , bifurcates subcritically from the lower branch of ONWB at $Re = 1077$, $Re_b = 468$ (filled circle), undergoes two turning points at $Re = 969$ and 1753 , and terminates on the upper branch of ONWB at $Re = 1483$, $Re_b = 490$ (open circle). This solution branch connects the bifurcation points indicated by the filled and open circles in figure 1. Another new solution, which results from the instability due to symmetry ID and possesses only symmetry Ω , bifurcates supercritically from the upper branch of ONWB at $Re = 1393$, $Re_b = 467$ (open inverted triangle in figure 3a and also in figure 2b). Comparison of figure 3(a) and figure 3(b) shows that the phase velocity is 30~50 % larger than the mean velocity for both ONWB and the two asymmetric solutions at fixed Re . We have used the truncation

FIGURE 4. The skin friction against the bulk Reynolds number for $\alpha = 1.14$. The curves and symbols are the same as figure 3. The laminar state is given by $\lambda = 28.45/Re_b$.

levels $(L, M, N) = (6, 33, 33)$ for both the S -symmetric solution and the Ω -symmetric solution after numerical convergence checks have been carried out (see tables 1 and 2). In the tables L corresponds to the number of Fourier modes in the axial direction, and M and N correspond to the maximum degrees of the modified Chebyshev polynomials in the square cross-section. The degrees of freedom (d.o.f.) are almost doubled when compared with the 6242 used for ONWB.

FIGURE 5. (a) The instantaneous flow and (b) the mean part of the disturbance of the $\mathcal{S}$ -symmetric solution with $\alpha = 0.5$, $Re = 3315$ ($Re_b = 1468$). The velocities on the y - z plane and in the x -direction are indicated by the arrows and the colourscale, respectively.

3.1. $\mathcal{S}$ -symmetric solution

The instantaneous flow of the disturbance of the $\mathcal{S}$ -symmetric solution at $\xi \equiv x - ct = 5\pi/8$ with an appropriate choice of the initial phase and the mean part of the disturbance for $\alpha = 0.5$ at $Re = 3315$ are shown in figure 5(a) and figure 5(b), respectively. The mirror-symmetry with respect to $z = 0$ of ONWB is broken and strong disturbances, which are composed of a pair of quasi-streamwise vortices and a low-speed streak, are observed near the sidewall $z = +1$. The solution which has the same structures near $z = -1$ is also a possibility by the symmetry of the system. The mean flow is mirror-symmetric with respect to $y = 0$ (taking the streamwise average of (2.1) leads to the symmetry for the mean flow: $(\bar{U}, \bar{V}, \bar{W})(y, z) = (\bar{U}, -\bar{V}, \bar{W})(-y, z)$, where $\bar{U} = \int_0^{2\pi/\alpha} u dx$, etc.). The flow structures of this solution exhibit a striking similarity to those of the asymmetric solution in a pipe by Pringle & Kerswell (2007) (see the top frames of their figure 1). These two asymmetric solutions possess the shift-and-reflect symmetry in common. Strong similarity for the two solutions is also observed in the skin friction (compare figure 4 with their figure 6). The existence domains of the $\mathcal{S}$ -symmetric solution are shown in figure 6. We can see that for each of the three cases, $Re = 950, 1000, 1050$, the lower and the upper branches of ONWB corresponding to the upper and lower parts of the closed loop are connected by the $\mathcal{S}$ -symmetric solution, indicated by a curve with the open and filled circles at its end points on the loop. The existence domain has more turning points on the α - Re_b plane as the Reynolds number increases, which indicates that the number of solutions increases for a fixed wavenumber. The $\mathcal{S}$ -symmetric travelling wave emerges first in the α - Re_b plane at $\alpha = 1.36$, $Re = 924$ ($Re_b = 374$) and the minimum bulk Reynolds number is 365 at $\alpha = 1.38$, $Re = 952$.

The mean flow of our $\mathcal{S}$ -symmetric solution resembles that of the edge state in the square-duct flow in Biau & Bottaro (2009) (compare figure 5(b) with their figure 6). We also examine other flow properties of the $\mathcal{S}$ -symmetric solution to see whether the solution matches with the edge state identified in Biau & Bottaro (2009), which

FIGURE 6. The existence domains of the $\mathcal{S}$ -symmetric solutions at $Re = 950, 1000, 1050$. The dotted loops indicate ONWB. The filled (open) circles represent the bifurcation points on the lower (upper) branch.

Solution	λ	Re_b	E_U
$\mathcal{S}$ -symmetric	0.02087	1468 (2937)	1.439×10^6 (255.8)
ONWB, lower	0.02099	1464 (2928)	1.429×10^6 (254.1)
WBN, lower	0.03459	1145 (2290)	8.172×10^5 (145.3)
UKP, lower	0.02568	1324 (2648)	1.120×10^6 (199.1)

TABLE 3. The skin friction λ , bulk Reynolds number Re_b and energy of the streamwise-averaged flow $E_U = (1/4) \int_{-1}^{+1} \int_{-1}^{+1} (\bar{U}^2 + \bar{V}^2 + \bar{W}^2)/2 \, dy \, dz$ of the travelling waves with $Re = 3315, \alpha = 0.5$. The values in the brackets are normalized by the scales adopted in Biau & Bottaro (2009). The solutions reported in Wedin *et al.* (2009) and Uhlmann *et al.* (2010) are referred to as WBN and UKP, respectively.

lies within $0.021 \lesssim \lambda \lesssim 0.024$, $2720 \lesssim Re_b \lesssim 2900$ and $214 \lesssim E_U \lesssim 250$, where E_U is the energy of the streamwise-averaged flow (see their figures 5 and 7). The properties of the $\mathcal{S}$ -symmetric solution and the lower branches of other travelling wave solutions obtained elsewhere with $\alpha = 0.5$ for $Re = 3315$ (this parameter corresponds to $\alpha = 1.0, Re_\tau = 150$ in the notation of Biau & Bottaro 2009) are listed in table 3. From table 3 we see that the $\mathcal{S}$ -symmetric solution and ONWB take the values for λ , Re_b and E_U almost within the ranges of the edge state, while WBN and UKP have rather higher friction and lower energy and bulk Reynolds number than the edge state. It is found that the $\mathcal{S}$ -symmetric solutions have a fewer unstable eigenvalues and the values themselves are smaller than those of ONWB when linear stabilities of these flows are compared to all possible forms of perturbations (see table 4). The asymmetric structure and the few and low-valued positive eigenvalues associated with the $\mathcal{S}$ -symmetric solution indicate that the $\mathcal{S}$ -symmetric solution matches, more adequately than ONWB in phase space, with the quasi-stable edge state in

Asymmetric travelling waves in a square duct

Biau & Bottaro (2009) where the vortical structure prefers one of the sidewalls and stays there for a while before moving to the other side. It can be expected that the edge state of square-duct flow is formed around the $\mathcal{S}$ -symmetric solutions and their heteroclinic connections (four $\mathcal{S}$ -symmetric solutions exist due to the rotational symmetry by 90°) similar to those shown in Duguet *et al.* (2008b) for pipe flow. It should be noted that the edge state of pipe flow also consists of a pair of streamwise vortices located off centre (for instance, see Schneider *et al.* 2007).

3.2. Ω -symmetric solution

The velocity field of the Ω -symmetric solution is shown in figure 7. The Ω -symmetric solution almost looks like the ONWB solution (see their figure 11), but the mirror-symmetry $\mathcal{Z}$ with respect to $z = 0$ is broken as can be seen in figure 7. The bifurcation of this solution is of pitchfork type, producing a pair of solutions as shown in figure 8. We can see in figure 8(a), for one of the two solutions, that the vortices with negative vorticity are elongated in the streamwise direction more than those with positive vorticity. Figure 8(b), for the other solution, shows an opposite structure. The existence domains of the Ω -symmetric solution are shown in figure 9. The solution appears first at $\alpha = 1.43$, $Re = 1271$ ($Re_b = 427$). At a slightly larger Reynolds number,

FIGURE 8. A pair of the Ω -symmetric solutions with $\alpha = 1.43$, $Re = 1400$ ($Re_b = 461$). The iso-surfaces, red (blue) and green, show +70 % (−70 %) of the maximum streamwise vorticity and 40 % of the maximum streamwise velocity, respectively.

FIGURE 9. The existence domains of the Ω -symmetric solutions at $Re = 1280, 1330, 1380$. The dotted curves indicate ONWB. The inverted triangles represent the bifurcation points.

the Ω -symmetric solution begins to connect with the upper branch of ONWB via a pitchfork bifurcation (open inverted triangles). The counterpart of this solution in pipe flow has not been reported yet.

4. Conclusion

We have performed a linear stability analysis of the mirror-symmetric solution obtained by Okino *et al.* (2010), and found the neutral points with a real eigenvalue. Two asymmetric travelling wave solutions, which emerge through a pitchfork bifurcation from the neutral points, are obtained. One of them, the S -symmetric solution, retains the shift-and-reflect symmetry, and is characterized by a pair of streamwise vortices and a low-speed streak attached to one of the sidewalls. The solution seems to be embedded in the laminar–turbulent boundary found by Biau & Bottaro (2009).

The similarity in bifurcation nature between square-duct flow and pipe flow shown in this paper implies that these two pressure-driven flows become turbulent through a common mechanism despite the difference between their cross-sectional geometries. The presence of the corners of the square duct does not seem to play a crucial role in transition to turbulence.

The other, Ω -symmetric solution, retains the shift-and-rotate symmetry. This solution deviates slightly from ONWB. It is plausible that the counterpart of the Ω -symmetric solution exists also in pipe flow.

Our stability analysis shows that many solutions could emerge far below the transitional Reynolds number, $Re_b \sim 1000$, via symmetry-breaking bifurcations (mainly from the upper branch), showing the richness of the nonlinear solutions and the complexity of phase-space dynamics in the transitional regime. Solutions which bifurcate from neutral points with the complex eigenvalue are not considered here. These solutions are expected to be time-periodic in the frame of reference moving with a constant speed and might be captured numerically by using a time-stepping code.

Okino (2011) investigated localized vortex structures by smoothly changing the aspect ratio, A . A single vortex state persisted for ONWB at least for $A < 5$. Further investigations would be required to detect a snaking instability (Schneider, Gibson & Burke 2010) for larger aspect ratios. Also, the asymmetric states of Itano & Toh (2000) in plane Poiseuille flow could be recovered by our asymmetric travelling wave solutions for asymptotically large aspect ratios. A set of solutions other than those presented here could also be found in Okino (2011), where the solutions were obtained by the self-sustaining process method (Wedin *et al.* 2008).
