We compute one- and two-loop quadratic divergent contributions to the bare Higgs mass in terms of the bare couplings in the Standard Model. We approximate the bare couplings, defined at the ultraviolet cutoff scale, by the \( \overline{\text{MS}} \) ones at the same scale, which are evaluated by the two-loop renormalization group equations for the Higgs mass around 126 GeV in the Standard Model. We obtain the cutoff scale dependence of the bare Higgs mass, and examine where it becomes zero. We find that when we take the current central value for the top quark pole mass, 173 GeV, the bare Higgs mass vanishes if the cutoff is about \( 10^{25} \) GeV. With a 1.3 \( \sigma \) smaller mass, 170 GeV, the scale can be of the order of the Planck scale.

The tuning may be accounted for by quantum gravitational nonperturbative effects such as those from a multiverse or baby universe; see, e.g., Ref. [12]. There are yet other discussions that the tuning is achieved within the context of field theory such as the classical conformal symmetry; see, e.g., Ref. [13].

In this paper, we do not try to solve the naturalness problem. Rather, we evaluate the value of the bare parameters in order to investigate the Planck scale physics. They must be useful to connect the low energy physics to the underlying microscopic description, such as string theory.

In this paper, we compute the bare Higgs mass by taking into account one- and two-loop corrections in the SM. When we write in terms of the dimensionless bare couplings, the bare Higgs mass turns out to be a sum of a quadratically divergent part (\( \propto \Lambda^2 \)), which is independent of the physical Higgs mass, and a logarithmically divergent one (\( \propto \log \Lambda \)). The importance of the coefficient of \( \Lambda^2 \) was first pointed out by Veltman at the one-loop order [14].

Generalizations to higher loops within the renormalized perturbation theory have been developed and applied in Ref. [15] in which the authors have reported the behavior \( \sim \Lambda^2 (\log \Lambda)^n \); see also Ref. [16] for a review. In contrast, we see that such behavior does not appear in the bare perturbation theory. The reason why we employ the latter framework is that we are interested in the scale near the cutoff. These points will be discussed in detail with explicit calculations in Sec. II.

We will see that the bare mass can be zero if \( \Lambda \) is around the Planck scale, which gives some interesting suggestions on the Planck scale physics. First, it may imply that the supersymmetry of the underlying microscopic theory is restored above the Planck scale. In fact, superstring theory has many phenomenologically viable perturbative vacua in which supersymmetry is broken at the Planck scale; see, e.g., Ref. [17]. In the last section, we will discuss that threshold corrections at the string scale may generate a small nonvanishing bare mass. Second, the vanishing of the bare Higgs mass together with that of the quartic Higgs coupling indicates almost flat potential near the Planck...
scale, which opens a possibility that the slow-roll inflation is achieved solely by the Higgs potential \[18\].

This paper is organized as follows. In the next section, we explain our convention and calculate the quadratic divergent contributions to the bare Higgs mass up to the two-loop orders. In Sec. III, we present a renormalization group equation (RGE) analysis in the SM and give our results for the Higgs quartic coupling at high scales. In Sec. IV, we examine how small the bare Higgs mass can be at the Planck scale and show at what scale the bare Higgs mass vanishes. We vary \(\alpha_s\), \(m_H\), and \(m_t^{\text{pole}}\) to see how the results are affected. The last section contains the summary and discussions.

II. BARE HIGGS MASS

In this section, we compute the quadratic divergence in the bare Higgs mass.

A. Bare mass in \(\phi^4\) theory

Let us explain our treatment of the bare mass by taking a simple example of the \(\phi^4\) theory with the bare Lagrangian:

\[
\mathcal{L} = \frac{1}{2} \left( \partial_\mu \phi_B \right)^2 - \frac{m_B^2}{2} \phi_B^2 - \frac{\lambda_B}{4!} \phi_B^4. \tag{2}
\]

In the mass independent renormalization scheme,\(^1\) the bare mass \(m_{B,0}\) is separated into the quadratically divergent part \(\Delta_{\text{sub}}\) and the remaining one \(m_0^2\):

\[
m_{B,0}^2 = \Delta_{\text{sub}} + m_0^2. \tag{3}
\]

Here \(\Delta_{\text{sub}}\) is chosen in such a way that the physical mass becomes zero when \(m_0^2 = 0\). Then the mass parameter \(m_0^2\) is introduced to describe the deviation from it and is multiplicatively renormalized to absorb the logarithmic divergence. We note that in the dimensional regularization, \(\Delta_{\text{sub}}\) happens to be formally zero and only \(m_0^2\) remains.\(^2\) What we discuss in this paper is not \(m_0^2\) but the whole \(m_{B,0}^2\). Since \(m_{B,0}^2\) is negligibly small compared to \(\Delta_{\text{sub}}\), we concentrate on the quadratically divergent part \(\Delta_{\text{sub}}\) in the following.

From the bare Lagrangian (2), we calculate the bare mass \(m_{B,0}\) order by order in the loop expansion so that the physical mass is tuned to be zero\(^3\):

\[
m_{B,0}^2 = m_{B,0}^2 + m_{B,1}^2 + m_{B,2}^2 + \cdots. \tag{4}
\]

At each order, we fix the bare mass as

\[
m_{B,0}^2 = 0, \tag{5}
\]

\[
m_{B,1}^2 + i \left( \begin{array}{c} \hline \end{array} \right) \left. \right|_{k=0} = 0, \tag{6}
\]

\[
m_{B,2}^2 + i \left( \begin{array}{c} \hline \end{array} \right) \left. \right|_{k=0} = 0. \tag{7}
\]

The one-loop integral in Eq. (6) is quadratically divergent and is proportional to

\[
I_1 := \int \frac{d^4 p_E}{(2\pi)^4} \frac{1}{p_E^4}, \tag{8}
\]

where \(p_E\) is a Euclidean four momentum. In the two-loop computation (7), the momentum integrals in the third and fourth terms are, respectively,

\[
J_2 := \int \frac{d^4 p_E}{(2\pi)^4} \frac{d^4 q_E}{(2\pi)^4} \frac{1}{p_E^4 q_E^4 (p_E^2 + q_E^2)^2}, \tag{9}
\]

\[
I_2 := \int \frac{d^4 p_E}{(2\pi)^4} \frac{d^4 q_E}{(2\pi)^4} \frac{1}{p_E^4 q_E^4 (p_E^2 + q_E^2)^2}. \tag{10}
\]
The integral $J_2$ is infrared (IR) divergent: $J_2 \propto \Lambda^2 \ln(\Lambda/\mu_{IR})$ but is canceled by the second term in Eq. (7) due to the lower order condition (6). Therefore, we are left with only $I_2$, which does not suffer from the infrared divergence. This situation does not change in higher orders because a mass should not contain an IR divergence.

**B. Bare mass in SM**

For the SM Higgs sector, we start from the bare Lagrangian of the following form in a fixed cutoff scheme with cutoff $\Lambda$: 4

$$\mathcal{L} = (D_\mu \phi_B)^\dagger (D^\mu \phi_B) - m_B^2 \phi_B^\dagger \phi_B - \lambda_B (\phi_B^\dagger \phi_B)^2.$$  

$$\phi_B = \left( \begin{array}{c} \phi_B^\dagger \\ \phi_B \end{array} \right).$$  

(11)

We set the physical mass to be zero: $m_{B,0-loop}^2 = 0$, as we are interested in physics at very high scales. 5 The Planck scale is

$$M_{Pl} = \frac{1}{\sqrt{\alpha_N}} = 1.22 \times 10^{19} \text{ GeV}.$$  

(12)

We take into account the SM couplings $g_Y, g_2, g_3, \lambda, \gamma$, and neglect the others.

Now let us follow the prescription, shown in the previous subsection, in the SM. In the following, we work in the symmetric phase $\langle \phi \rangle = 0$ as we are interested only in the quadratic divergent terms. In the evaluation of the Feynman diagrams, it is convenient to take the Landau gauge for all the $SU(3) \times SU(2) \times U(1)$ gauge fields. In this gauge, a diagram always vanishes if an external Higgs line is attached with a gauge boson propagator by a three-point vertex:

$$\int \frac{d^4k}{k^2} = 0.$$  

(13)

From the one-loop diagrams we get the quadratic divergent integral $I_1$ again [14]:

$$m_{B,1-loop}^2 = - \left( 6\lambda_B + \frac{3}{4}g_Y^2 + \frac{9}{4}g_{2B}^2 - 6\gamma_{2B}^2 \right) I_1.$$  

(14)

In Fig. 1, we present the two-loop Feynman diagrams that do not vanish in the symmetric phase $\langle \phi \rangle = 0$ and in the Landau gauge. In the second row of Fig. 1, the last diagram cancels the divergences coming from the one-loop self-energy of the internal Higgs propagators, as in Eq. (7). 6 All the momentum integrals can be recast into either $I_2$ or $J_2$. 7 We have explicitly checked that the coefficients of the infrared divergent integral $J_2$ cancel in each gauge invariant set of diagrams.

The two-loop contribution to the bare mass at $\Lambda$ becomes 8

$$m_{B,2-loop}^2 = - \left[ 9g_{1B}^2 + \frac{7}{12}g_Y^2 + \frac{9}{4}g_{2B}^2 - 16g_{3B}^2 \right] I_2.$$  

(15)

This is one of our main results. Note that Eqs. (14) and (15) are minus the radiative corrections to the physical Higgs mass squared; see Eqs. (6) and (7).

In Sec. IV, we will examine whether the bare mass can vanish at a particular UV cutoff scale. For that purpose, we need to relate the integrals $I_1$ and $I_2$. This relation necessarily depends on the cutoff scheme. 9 In particular, if the two-loop contribution to the bare mass $m_{B,2-loop}^2$ becomes sizable compared to $m_{B,1-loop}^2$, the result suffers from a large theoretical uncertainty. We will verify that it is actually small. With this caution in mind, let us employ the following regularization:

$$\int d^4k_E \frac{1}{k_E^2} = \int \alpha d\alpha \int d^4k_E e^{-\alpha k_E^2},$$  

(16)

which gives

---

4 In general, the effective Lagrangian of an underlying microscopic theory at the cutoff scale contains higher dimensional operators. Their effects can be absorbed by the redefinition of the renormalizable and super-renormalizable couplings in the low energy region. Therefore it suffices to take the form of Eq. (11) without higher dimensional operators in order to reproduce the low energy physics. However, the differences among the bare theories emerge when the energy scale gets close to the cutoff $\Lambda$.

5 We are not intending to realize the Coleman-Weinberg mechanism, but to neglect the physical mass that is unimportant for our consideration.

6In practice, from each diagram containing a self-energy correction, one subtracts a term that is obtained by setting the external momentum of its self-energy to zero. We have also applied this subtraction for diagrams containing a vacuum polarization. For the gauge boson, this subtraction introduces a bare mass, which becomes zero in a gauge invariant regularization scheme such as the Pauli-Villars or dimensional regularizations.

7Gauge invariance is formally satisfied in the sense that the Ward-Takahashi identity holds if we shift momenta freely without worrying about the ultraviolet divergences. In this paper, we are interested in the quadratic divergences that are left after these momentum redefinitions.

8As mentioned in Ref. [14], while at the one-loop level, only a restricted set of particles participates; on the two-loop level, all kinds of particles up to the Planck mass enter in the discussion. We assume that there appear only SM degrees of freedom up to the UV cutoff scale.

9One can rigorously compute both $I_1$ and $I_2$ in principle if one fixes a cutoff scheme, such as an embedding in string theory. For our purpose, the simplified procedure (16) suffices as we just want to check the smallness of the two-loop contributions.
When we employ a naive momentum cutoff by $\Lambda$, we get
$$I_1 = \frac{\Lambda^2}{16\pi^2},$$
(18)
and hence we can regard $1/e = \Lambda^2$.

C. Graviton effects

Let us estimate the graviton loop effects on the above obtained result. The graviton $h_{\mu\nu}$ in the metric
$$g_{\mu\nu} = \eta_{\mu\nu} + \frac{\sqrt{32\pi}}{M_{Pl}} h_{\mu\nu}$$
(19)
couples to the Higgs through the energy-momentum tensor:
$$T_{\mu\nu} = \frac{2}{\sqrt{-g}} \frac{\delta}{\delta g_{\mu\nu}} \sqrt{-g} L$$
$$= (D_{\mu} \phi)^\dagger (D_{\nu} \phi) + (D_{\nu} \phi)^\dagger (D_{\mu} \phi)$$
$$- g_{\mu\nu} [(D_{\mu} \phi)^\dagger (D^{\nu} \phi) - m_B^2 \phi^\dagger \phi - \lambda (\phi^\dagger \phi)^2].$$
(20)

The most divergent contributions come from two derivative couplings. A one-loop diagram containing such a graviton coupling vanishes because it necessarily picks up an external momentum, which is set to zero. Other contributions are at most logarithmically divergent. At the two-loop level, diagrams involving an internal graviton line that does not touch a Higgs external line give a form $\Lambda^4/M_{Pl}^2$. If the UV cutoff is much smaller than the Planck scale, this becomes negligible, and the higher loops become further insignificant. Indeed, in perturbative string theory, higher loop corrections are proportional to powers of the string coupling constant $g_s$ and become subleading. If the cutoff scale exceeds the Planck scale, we cannot neglect the graviton contributions.

III. SM RGE EVOLUTION TOWARD PLANCK SCALE

In Sec. IV, we will approximate the dimensionless bare coupling constants in the SM at the UV cutoff scale $\Lambda$ by the running ones in the modified minimal subtraction ($\overline{MS}$) scheme at the same scale $\Lambda$; see the Appendix for its justification. We note that the $\overline{MS}$ couplings will be used solely to approximate the dimensionless bare couplings at the cutoff scale and that the bare Higgs mass does not run.
To get the $\overline{\text{MS}}$ running coupling constant, we apply the RGE at the two-loop order. For $g_Y, g_2, g_s$, and $y_t$, we use the ones in Ref. [20].\footnote{We replace $g_1$ of the GUT normalization to $g_Y = \sqrt{3}/5g_1$ and rewrite the quartic coupling as $\lambda_{[20]} = 2\lambda$, where $\lambda_{[20]}$ is the one employed in Ref. [20].} For the quartic coupling, we employ the one given in Ref. [21].\footnote{We use the arXiv version 2 of Ref. [21] with the replacements $g' = g_Y, g = g_2, h = y_t$, and $\lambda_{[21]} = 6\lambda$, where $\lambda_{[21]}$ is the quartic coupling employed in Ref. [21]. The RGE for $\lambda$ in Ref. [20] becomes equal to that of Ref. [21], after correcting $-\frac{1}{2}g^3Y_1(S)$ to $-\frac{1}{2}g^2Y_2(S)$ and changing the part $\frac{\lambda}{2}\tau^2 + \frac{3}{2}n_s$ to $\frac{2\lambda}{2\tau} + \frac{1}{2}n_s$ in Eq. (A.17) in Ref. [20].} To be explicit,

\[
\begin{align*}
\frac{dg_Y}{dt} &= \frac{1}{16\pi^2} \frac{41}{6} g_Y^3 + \frac{3}{(16\pi^2)^2} \left[ \frac{199}{18} g_Y^2 + \frac{9}{2} g_2^2 + \frac{44}{3} g_s^2 - \frac{17}{6} y_t^2 \right], \\
\frac{dg_2}{dt} &= -\frac{1}{16\pi^2} \frac{19}{6} g_Y^3 + \frac{g_2^3}{(16\pi^2)^2} \left[ \frac{3}{2} g_Y^2 + \frac{35}{6} g_2^2 + 12 g_s^2 - \frac{3}{2} y_t^2 \right], \\
\frac{dg_s}{dt} &= -\frac{7}{16\pi^2} g_Y^3 + \frac{g_s^3}{(16\pi^2)^2} \left[ \frac{11}{6} g_Y^2 + \frac{9}{2} g_2^2 - 26 g_s^2 - 2 y_t^2 \right], \\
\frac{dy_t}{dt} &= \frac{y_t}{16\pi^2} \left[ \frac{9}{12} g_Y^2 - \frac{17}{12} g_2^2 - \frac{9}{4} g_s^2 - 8 g_s^2 \right] + \frac{y_t}{(16\pi^2)^2} \left[ -12 y_t^2 + 6 \lambda^2 - 12 \lambda y_t^2 + \frac{131}{16} g_Y^2 y_t^2 + \frac{225}{16} g_2^2 y_t^2 + \frac{36}{25} g_Y^2 y_t^2 + \frac{1187}{216} g_2^2 y_t^2 - \frac{23}{4} g_2^2 + \frac{108}{55} g_Y^2 + \frac{19}{9} g_s^2 y_t^2 \right]. \\
\frac{d\lambda}{dt} &= \frac{1}{16\pi^2} \left[ 24 \lambda^2 + 3 g_Y^2 \lambda - 9 g_Y^2 \lambda + \frac{3}{8} g_Y^4 + \frac{3}{4} g_Y^2 g_2^2 + \frac{9}{8} g_2^2 + 12 \lambda y_t^2 - 6 y_t^2 \right] + \frac{1}{(16\pi^2)^2} \left[ -312 \lambda^3 + 36 \lambda^2 (g_Y^2 + g_2^2) - \lambda \left( \frac{629}{24} g_Y^2 - \frac{39}{4} g_Y^2 g_2^2 + \frac{73}{8} g_2^4 \right) + \frac{305}{16} g_2^2 - \frac{289}{48} g_Y^2 g_2^2 - \frac{559}{48} g_Y^4 g_2^2 - \frac{379}{48} g_Y^2 g_2^2 - \frac{32}{3} g_Y^2 y_t^2 - \frac{8}{3} g_2^2 y_t^2 - \frac{9}{4} g_2^2 y_t^2 + \lambda y_t^2 \left( \frac{85}{6} g_Y^2 - \frac{45}{2} g_2^2 + 80 g_2^3 \right) + g_Y^2 y_t^2 \left( -\frac{19}{4} g_Y^2 + \frac{21}{2} g_2^2 \right) - 144 \lambda^2 y_t^2 - 3 \lambda y_t^2 + 30 y_t^2 \right].
\end{align*}
\]

where $t = \ln \mu$. Though we do not include the bottom and tau Yukawa couplings in this paper, we have checked that these are negligible within the precision that we work in.

We put the boundary condition for the RGE (21) according to Ref. [5]. The $\overline{\text{MS}}$ gauge coupling of $SU(3)$ is given by the three-loop RGE running from $m_Z$ to $m_t$ and matching with six flavor theory as [5]

\[
g_s(m_t^{\text{pole}}) = 1.1645 + 0.0031 \left( \frac{\alpha_s(m_Z) - 0.1184}{0.0007} \right) - 0.00046 \left( \frac{m_t^{\text{pole}}}{\text{GeV}} - 173.15 \right).
\]

where $m_t^{\text{pole}}$ is the pole mass of the top quark. The $\overline{\text{MS}}$ quartic coupling at the top pole mass $m_t^{\text{pole}}$ is given by taking into account the QCD and Yukawa two-loop corrections [5]

\[
\lambda(m_t^{\text{pole}}) = 0.12577 + 0.00205 \left( \frac{m_H^{\text{pole}}}{\text{GeV}} - 125 \right) - 0.00004 \left( \frac{m_t^{\text{pole}}}{\text{GeV}} - 173.15 \right) \pm 0.00140_{\text{th}},
\]

where $m_H$ is the observed Higgs mass which we read off from Eq. (1) as

\[
m_H = 125.7 \pm 0.6 \text{ GeV}.
\]

The $\overline{\text{MS}}$ top Yukawa coupling at the scale $m_t^{\text{pole}}$ is given by taking into account the QCD three-loop, electroweak one-loop, and $O(\alpha_s \alpha)$ two-loop corrections [5]:

\[
y_t(m_t^{\text{pole}}) = 0.93587 + 0.00557 \left( \frac{m_t^{\text{pole}}}{\text{GeV}} - 173.15 \right) - 0.00003 \left( \frac{m_H}{\text{GeV}} - 125 \right) - 0.00041 \left( \frac{\alpha_s(m_Z) - 0.1184}{0.0007} \right) \pm 0.00200_{\text{th}}.
\]

In a more recent work [6], it has been pointed out that the error in the top quark pole mass, consistently derived from the running one, is larger than that given in Ref. [5], $173.1 \pm 0.7 \text{ GeV}$. The value obtained is [6]

\[
m_t^{\text{pole}} = 173.3 \pm 2.8 \text{ GeV},
\]

which we will use in our analysis.

We plot the $\overline{\text{MS}}$ running coupling constant $\lambda(\mu)$ in Fig. 2. As we increase the scale $\mu$, the coupling $\lambda$ first decreases due to the term $-6y_t^2$ and remains small above $\mu = 10^{10}$ GeV for a while. At further higher energies, $y_t$ becomes smaller and $\lambda$ starts to increase due to the contribution from $\frac{1}{2}g_Y^4$ which is not asymptotically free. At the intermediate scale, $\lambda$ can become negative, but it is shown...
that a metastability condition can be met even in this case [4–6].\textsuperscript{12} The value of $\lambda$ at the Planck scale $M_{Pl}$ becomes consistent with Eq. (64) in Ref. [5]:

$$\lambda(M_{Pl}) = -0.014 - 0.018 \left( \frac{m_t^{pole} - 173.3 \text{ GeV}}{2.8 \text{ GeV}} \right) + 0.002 \left( \frac{\alpha_s(m_Z) - 0.1184}{0.0007} \right) + 0.002 \left( \frac{m_H - 125.7 \text{ GeV}}{0.6 \text{ GeV}} \right) \pm 0.004_{\text{th}}.$$  \hspace{1cm} (27)

As we can see from the left panel in Fig. 2, the value of the quartic coupling stays around its minimum in $10^{15}$ GeV $\leq \mu \leq 10^{20}$ GeV. Therefore, the minimum value of $\lambda$ is also given by Eq. (27) within our precision. In the right panel in Fig. 2, we plot $\mu_{min}$ at which the $\lambda(\mu)$ takes its minimum value. The central value $m_t^{pole} = 173.3$ GeV gives $\mu_{min} = 4 \times 10^{17}$ GeV.

\section*{IV. BARE HIGGS MASS AT PLANCK SCALE}

Now we can estimate the bare Higgs mass at the cutoff scale by substituting the \overline{MS} couplings derived in the previous section to the bare ones in the right-hand sides of Eqs. (14) and (15).

In the left panel of Fig. 3, we plot the dependence of the bare Higgs mass-squared in units of $\Lambda^2/16\pi^2$ on the UV cutoff scale $\Lambda$:

$$\frac{m_H^2}{\Lambda^2/16\pi^2} = \frac{m_{H,1-\text{loop}}^2}{I_1} + \frac{m_{H,2-\text{loop}}^2}{I_2} I_2 / I_1,$$  \hspace{1cm} (28)

where we have taken $I_2/I_1 = 0.005$ as in Eq. (17). In the figure, we can see that the bare mass $m_H^2$ monotonically decreases when one increases $\Lambda$.\textsuperscript{13}

We obtain the UV cutoff scale at which the bare mass $m_H^2$ becomes zero:

$$\log^{10} \frac{\Lambda}{m_H^2 = 0} \text{ GeV} = 23.5 + 3.3 \left( \frac{m_t^{pole} - 173.3 \text{ GeV}}{2.8 \text{ GeV}} \right) - 0.2 \left( \frac{m_H - 125.7 \text{ GeV}}{0.6 \text{ GeV}} \right) - 0.4 \left( \frac{\alpha_s(m_Z) - 0.1184}{0.0007} \right) \pm 0.4_{\text{th}}.$$  \hspace{1cm} (29)

In the right panel of Fig. 3, we plot this quantity as a function of the top quark pole mass for the central values of $\alpha_s(m_Z)$ and $m_H$, without referring to the linear approximation (29).

We show an approximate formula for the bare Higgs mass when the cutoff is at the Planck scale, $\Lambda = M_{Pl}$:

$$m_H^2 = \left[ 0.22 + 0.18 \left( \frac{m_t^{pole} - 173.3 \text{ GeV}}{2.8 \text{ GeV}} \right) - 0.02 \left( \frac{\alpha_s(m_Z) - 0.1184}{0.0007} \right) - 0.01 \left( \frac{m_H - 125.7 \text{ GeV}}{0.6 \text{ GeV}} \right) \pm 0.02_{\text{th}} \right] M_{Pl}^2/16\pi^2.$$  \hspace{1cm} (30)

This is one of our main results. We verify that the two-loop correction (15) can be safely neglected: $m_{H,2-\text{loop}}^2 \approx -0.005M_{Pl}^2/16\pi^2$ within the cutoff scheme (17), as advertised before. In Fig. 4, we plot the bare Higgs mass-squared in units of $M_{Pl}^2/16\pi^2$ as a function of $m_t^{pole}$ for the central values of $\alpha_s(m_Z)$ and $m_H$, without referring to the linear

\textsuperscript{12}At first sight, $\lambda_H < 0$ seems to indicate a runaway potential. In the SM, radiative corrections from the top quark loop generates a potential barrier. The metastability argument does not assume an existence of a true stable vacuum at a very high scale but computes the vacuum decay rate from the area of the potential barrier from $\phi = 0$ to the other zero point. In our case, it is possible that the runaway potential can be cured for a negative but small coupling ($\lambda_H < 0, |\lambda_H| \ll 1$) by the higher dimensional operators with positive couplings, such as $|\phi|^{\alpha}/\Lambda^2$, which become important near the cutoff scale $\Lambda$. See also footnote 4.

\textsuperscript{13}We note again that the bare Higgs mass is defined for each UV cutoff $\Lambda$ and is not a running quantity.
We have presented a procedure where the quadratic divergence of the bare Higgs mass is computed in terms of the bare couplings at a UV cutoff scale $\Lambda$. Using it, we have obtained the bare Higgs mass up to the two-loop order in the SM. This calculation has been made easier by working in the symmetric phase $\langle \phi \rangle = 0$ and in the Landau gauge. We have checked that all the IR divergent terms, which are proportional to $\Lambda^2 \ln(\Lambda/\mu_{IR})$, cancel out as expected. Approximating the bare couplings at $\Lambda$ by the corresponding $\overline{\text{MS}}$ ones at the same scale, we can examine whether the quadratic divergence in the bare Higgs mass vanishes or not. To get the $\overline{\text{MS}}$ couplings at high scales, we employ the two-loop RGE in the SM. We have found that it is indeed the case if the top quark mass is $m_t^{\text{pole}} = 169.8$ GeV, which is $1.3 \sigma$ smaller than the current central value. One might find it intriguing that this value is close to $m_t^{\text{pole}} = 171.2$ GeV, which gives a vanishing quartic coupling at $M_{Pl}$.

It is a curious fact that the scale of the vanishing bare Higgs mass $m_H^{\text{pole}}$ and that for the quartic coupling $\lambda$ are quite close to each other and to the Planck scale. The fact that the Planck scale appears only from the SM might indicate that the SM is indeed valid up to the Planck scale and is a direct consequence of an underlying physics there. Also, it may imply an almost flat potential near the Planck scale, which opens a possibility that the slow-roll inflation is achieved solely by the Higgs potential.

Note again that in this paper we are not trying to solve the fine-tuning problem but to determine all the bare parameters at the cutoff scale. In addition, we investigate the scale of the vanishing bare mass as a hint of that of the supersymmetry restoration.
If we take all the central values for $m^\text{pole}_H$, $\alpha_s(m_Z)$, and $m_H$, then the cancellation occurs not at the Planck scale but at a scale around $\Lambda \sim 10^{23}$ GeV. This may hint at a new physics around that scale. In this case, however, we need to take the graviton effects into account, as discussed in Sec. II C.

There can be a different interpretation for the small bare Higgs mass $m^2_H$ left at the Planck scale. It might appear as a threshold correction in string theory. In string theory, the tree-level masses of the particles are quantized by $m_x := (\alpha')^{-1/2}$, and therefore the Higgs mass is zero at the tree level. The threshold effect from integrating out the massive stringy excitations is obtained by computing insertions of two Higgs emission vertices with zero external momenta into the world sheet. The result would become

$$m^2_H \sim C \frac{g^2}{16\pi^2} m_Z^2,$$  

(31)

where $C$ is a model dependent constant. This calculation can be performed for a concrete model such as the orbifold and fermionic constructions in heterotic string. This work will be presented in a separate publication.

We comment on the case where the UV completion of the SM appears as a supersymmetry. When the supersymmetry is softly broken, there cannot be any quadratic divergence and our study does not apply. In the case of the high-scale/split supersymmetry [11,23] it is possible to perform a parallel analysis to the current one, which will be shown elsewhere.

If we assume the seesaw mechanism, the right-handed neutrinos are introduced above an intermediate scale $M_R$. Our analysis corresponds to the case where $M_R$ is small enough that all the neutrino Dirac-Yukawa couplings are negligible $y_D \lesssim 10^{-1}$. This condition implies $M_R \lesssim 10^{12}$ GeV for the neutrino mass $m_\nu \sim y_D^2 v^2 / M_R \sim 0.1$ eV. It would be interesting to extend our analysis to include larger Dirac-Yukawa couplings for $M_R \gtrsim 10^{12}$ GeV.

ACKNOWLEDGMENTS

We greatly appreciate valuable discussions with Satoshi Iso and useful information from him, without which this study would never have been started. O.) and for the Global COE program “The Next Generation of Physics, Spun from Universality and Emergence.”

APPENDIX

1. Cutoff vs $\overline{\text{MS}}$

We have approximated the dimensionless bare coupling constants in the SM by the running ones in the $\overline{\text{MS}}$ scheme at $\Lambda$. The resulting error can be evaluated once the cutoff scheme is explicitly specified.

More concretely, let us first express the $\overline{\text{MS}}$ couplings at a scale $\mu$ in terms of the bare couplings defined at the cutoff scale $\Lambda$:

$$\lambda^i_{\overline{\text{MS}}} (\mu) = \lambda^i_B + \sum_{jk} c^{ijk} (\mu / \Lambda) \lambda^j_B \lambda^k_B + O(\lambda^2_B),$$  

(A1)

$$c^{ijk} (x) := f^{ijk} + b^{ijk} \ln x + O(x^2),$$  

(A2)

where $b^{ijk}$ is the coefficient in the one-loop beta function and $f^{ijk}$ is the finite part from the one-loop diagrams. $\{ \lambda^i_{\overline{\text{MS}}} \}_{i = 1, \ldots, 5}$ stands for the $\overline{\text{MS}}$ (bare) couplings of the SM: $\{ g^2, g^2_\gamma, g^2_\gamma, g^2_\gamma, g^2_\gamma, g^2_\gamma, \lambda \}$.

In our case, the two-loop corrections in the RGE at high scales are small compared to the one-loop order, which indicates that the two-loop terms $O(\lambda^2_B)$ in Eq. (A1) are negligible, as we can take $\mu$ that satisfies both

$$\mu \ll \Lambda, \quad \left| \frac{\lambda^i_{\overline{\text{MS}}} (\mu)}{\mu} \ln \left( \frac{\mu}{\Lambda} \right) \right| \ll 1,$$  

(A3)

simultaneously. Thus we have

$$\lambda^i_{\overline{\text{MS}}} (\mu) = \lambda^i_B + \sum_{jk} b^{ijk} \lambda^j_B \lambda^k_B.$$  

(A4)

On the other hand, from the RGE, we get

$$\lambda^i_{\overline{\text{MS}}} (\Lambda) = \lambda^i_B + \sum_{jk} b^{ijk} \lambda^j_B \lambda^k_B,$$  

(A5)

From Eqs. (A5) and (A6), we obtain

$$\lambda^i_{\overline{\text{MS}}} (\Lambda) = \lambda^i_B + \sum_{jk} f^{ijk} \lambda^j_B \lambda^k_B,$$  

(A6)

which gives the relation between the bare and the $\overline{\text{MS}}$ couplings at the same scale.

With the above correction, the formula for the bare Higgs mass is modified by

$$\Delta m^2_H = - \sum_{ijk} a^{ij} f^{ijk} \lambda^j_{\overline{\text{MS}}} (\Lambda) \lambda^k_{\overline{\text{MS}}} (\Lambda),$$  

(A7)

where $a^{ij}$ are the coefficients in the one-loop bare Higgs mass $m^2_H = \sum a^i \lambda_B^i$ in Eq. (14), and are proportional to $I_i$. The scale at which the bare Higgs mass vanishes $\Lambda |_{m^2_H = 0}$ is changed to $\Lambda |_{m^2_H = 0} e^{\delta t}$, where

$$\delta t = \sum_{ijk} a^{ij} f^{ijk} \lambda^j_{\overline{\text{MS}}} (\Lambda) \lambda^k_{\overline{\text{MS}}} (\Lambda) / \sum_{ijk} a^{ij} b^{ijk} \lambda^j_{\overline{\text{MS}}} (\Lambda) \lambda^k_{\overline{\text{MS}}} (\Lambda).$$  

(A8)

Generically $f^{ijk}$ are of the same order as $b^{ijk}$ and hence the correction due to the replacement of the bare couplings by the $\overline{\text{MS}}$ ones, $\Delta m^2_H$, is as small as the two-loop corrections. Since $\delta t$ is of order unity, the ambiguity for the scale $\Lambda |_{m^2_H = 0}$ would be at most $e^{\delta t} \lesssim 10$.
