A diastereo- and enantioselective aldol reaction between aldehydes and a synthetically useful ketomalonate 1c as a hydrated form was developed, and either anti- or syn-aldol adducts having a chiral tetrasubstituted carbon center were obtained in high enantioselectivities by use of a tetrazole analogue of L-proline (S)-2 or an axially chiral amino sulfonamide (S)-3 as catalyst.

Asymmetric aldol reactions provide expedient access to optically active β-hydroxy carbonyl compounds that are fundamental chiral building blocks for a number of biologically active and pharmacologically important compounds. Among these reactions, catalytically asymmetric aldol reactions of ketone electrophiles afford tertiary alcohols, and a chiral tetrasubstituted carbon center is efficiently constructed with these methods. In the area of organocatalysis, the development of direct asymmetric aldol reaction has been the subject of intensive research over the last decade; however, reactive aldehydes were employed as electrophiles in the most amine-catalyzed aldol reactions. Although a number of asymmetric aldol reactions between ketone nucleophiles and ketone electrophiles have been developed, only a few examples of using aldehyde nucleophiles, which tend to be dimerized through the homo-aldol reaction, toward ketone electrophiles have been reported so far. Additionally, an efficient method for the stereoselective synthesis of both diastereomers of such aldol adducts from the same set of reactants by simply replacing the catalyst has been scarcely investigated. Accordingly, we have been interested in the development of organocatalytic asymmetric aldol reaction between aldehyde nucleophiles and ketone electrophiles based on the molecular recognition approach. The difficulty in developing the asymmetric aldol reaction of ketones can be attributed to the lower intrinsic electrophilicity of ketones over aldehydes, combined with the smaller steric difference between the two groups on the carbonyl moiety. To overcome the low reactivity of ketone acceptors, we chose ketomalonate 1, which is obtained in a hydrate form, as electronically activated ketone equivalent by two different modifiable ester groups (Fig. 1). One ester group of 1 consists of phenols, which are sterically demanding and sufficiently good leaving group, to induce diastereoselectivity as well as to discriminate two ester groups of 1. Herein, we wish to report both anti and syn-selective synthesis of chiral tertiary alcohols based on the molecular recognition approach from the stereocontrolled aldol reaction of the hydrated ketomalonate 1 having modifiable substituents with aldehydes catalyzed by either the tetrazole analogue of L-proline (S)-2 or an axially chiral amino sulfonamide of type (S)-3.

Fig. 1 Unsymmetrical ketomalonate 1 in a hydrate form for asymmetric cross-aldol reaction.

We first examined the effect of 2,6-substituents on phenyl group of hydrated ketomalonate 1 in the aldol reaction, and the results are summarized in Table 1. In the presence of 20 mol% of L-proline, the reaction between 3-phenylpropanal and 1a (Ar = 2,6-Me2-C6H3) in dichloromethane at room temperature proceeded smoothly to give the desired anti-aldol adduct anti-4a as major diastereomer in good yield with excellent enantioselectivity (entry 1). Unfortunately, however, 4a was found to be readily isomerized to a 1:1 mixture of the anti and syn-isomers after isolation. Use of a more hindered acceptors 1b (Ar = 2,6-Pr2-C6H3) and 1c (Ar = 2,6-2Me2-4Bu2-C6H3) resulted in higher anti-selectivity, and no isomerization was observed (entries 2 and 3). When the reaction of 1c was carried out with 10 mol% of catalyst (S)-2, the tetrazole derivative of L-proline, further improvement of anti-selectivity was achieved (entry 4).

Table 1 anti-Selective aldol reactions between 3-phenylpropanal and 1 catalyzed by L-proline.

![Table 1](image-url)
Having identified a suitable ketone acceptor, solvent screening was then carried out. The desired anti-aldol product anti-4c was formed as major diastereomer in good yield with excellent enantioselectivity in all solvents investigated (see Supplementary Information). Thus, toluene appeared to be the best solvent in terms of diastereoselectivity (Table 2, entry 3).

We then turned our attention to the development of the syn-selective aldol reaction of 1c catalyzed by an axially chiral amino sulfonamide (S)-3, which can switch the minor diastereomer in the reaction catalyzed by proline and its derivatives to the major diastereomer.\textsuperscript{11} In the presence of 5 mol\% of (S)-3, the reaction between 3-phenylpropanal and 1c in toluene at room temperature afforded the desired syn-aldol adduct syn-4c in good yield with high enantioselectivity (Table 2, entry 8). Among solvents tested, toluene was found to be a suitable solvent in terms of yield and syn-selectivity (see Supplementary Information).

With the optimal reaction conditions, the diastereo- and enantioselective aldol reaction of 1c with several other donor aldehydes was examined, and the results were summarized in Table 2. All reactions catalyzed by (S)-2 proceeded smoothly to give anti-aldol adducts as major diastereomer in good yield with excellent enantioselectivity (entries 1–5). Regardless of aldehyde structure, the diastereoselective outcome of the aldol adducts could be switched by using (S)-3 (entries 6–10).

The obtained aldol products anti-4c and syn-4c were versatile intermediates in organic synthesis and readily converted to important chiral building blocks such as γ-lactones. Thus, reduction of aldol product anti-4c with L-selectride at −78 °C and the subsequent lactonization with 1N HCl in one pot provided α-hydroxy-γ-lactone syn-5 in good yield without loss of the diastereoselectivity (Scheme 1). In the case of syn-4c, the corresponding α-hydroxy-γ-lactone anti-5 was readily obtained by treatment with L-selectride (Scheme 2). In both cases, the carbonyl group of more reactive aryl ester was preferentially incorporated into the lactone ring. A hydroxy group on anti-5 was converted to an amino group through mesylation, S$_2$2 reaction with NaN$_3$, and reduction under mild conditions.

Table 2. Aldol reactions of ketones with various aldehydes and 1c catalyzed by (S)-2 or (S)-3

Scheme 1 Synthesis of α-hydroxy-γ-lactone syn-5.

Scheme 2 Synthesis of α-hydroxy-γ-lactone anti-5 and α-amino-γ-lactone syn-7.

Based on the observed stereochemistry, transition state models can be proposed as shown in Figure 1. In the case of the reaction catalyzed by (S)-2, the activation and direction of the ketomalone 1c by the acidic functionality of (S)-2 is expected to occur by coordination to the sterically more accessible lone pair on the carbonyl oxygen atom of 1c. Consequently, the $Re$ face of ketomalone 1c approaches the
Re-face of the dominant s-trans-enamine, and the anti-aldol adduct was obtained as major diastereomer (Fig. 2, TS1). On the other hand, while both s-trans-enamine and s-cis-enamine might be formed in the reaction catalyzed by (S)-3, only s-cis-enamine can react with the activated ketonelatone 1c, giving the syn-aldol adduct predominantly (Fig. 2, TS2).  

![Fig. 2 Transition state models for the asymmetric aldol reaction catalyzed by (S)-2 (left) and (S)-3 (right).](image)

In summary, we have developed a diastereoselective and enantioselective direct aldol reaction of hydrated ketonelatone 1c with aldehydes catalyzed by proline derivative (S)-2 and the axially chiral amino sulfonamide (S)-3. This organocatalytic process represents a rare example of stereocontrolled aldol reaction between aldehyde donor and ketone acceptor. Further application of the present aldol reaction and the aldol reactions using other ketone acceptors are under investigation.
