FOSSIL ECHINOIDS DEPOSITED IN THE MUSEUM OF SETO MARINE BIOLOGICAL LABORATORY, SIRAHAMA, WAKAYAMA PREFECTURE
(ON SOME FOSSIL ECHINOIDS OF JAPAN, III)\(^1\)

AKIRA MORISHITA

Institute of Earth Sciences, Faculty of Science, Nagoya University

---

With 1 Plate, 3 Text-figures and 1 Table

Introduction and Acknowledgement

Several species of fossil echinoids from Wakayama Prefecture have been reported in various publications, and there are some specimens of fossil echinoids in the museum of Seto Marine Biological Laboratory (Kyoto University) at Sirahama, Wakayama Prefecture. The author had an opportunity to observe these specimens when he called on the Seto Marine Biological Laboratory, and he was recommended to describe them by Professor H. Utinomi of the Laboratory.

They are *Balanocidaris* sp. of the late Jurassic Period, *Enallaster yuasensis* Tanaka and Ókubo and *Enallaster* sp., of the early Cretaceous Period, and *Echinoneus cyclostomus* Leske of the middle Miocene Epoch, respectively.

The author wishes to acknowledge his indebtedness to Professor Huzio Utinomi and other members of the Seto Marine Biological Laboratory for their kind permission to examine the specimens.

Fossil Echinoids from Wakayama Prefecture with Geological Note

As far as known at present, species, ages and localities, of fossil echinoids from Wakayama Prefecture, are as the Table 1.

Cretaceous species had been described by K. Tanaka and M. Ókubo (1954) and Tertiary species, inserted by the author (1960) in the check list of the Japanese Tertiary echinoids. One of the Tertiary species, *Brissopsis makiyamai* Morishita had also been described by him, but another species, *Echinoneus cyclostomus* Leske, introduced by H. Utinomi (1954) at first without description.

Astriclypeus had been reported as one of several fossils from the Kanayama series by T. Takeyama, but it seems to be somewhat doubtful.

Besides, Schizaster? sp. is known from the Miyai series (Miocene) of Kitayama-mura, and an uncertain species of fossil echinoid, from the Kumano group (Miocene) of Nachi-Katsuura-cho in Wakayama Prefecture.

In this paper, Balanocidaris sp. is added newly in the above list.

The Torinosu formation (late Jurassic) distributes around the locality Balanocidaris sp. occurs. According to K. Tatebayashi, the Torinosu formation is divided into five members and the lowest, called the Mizukoshi member. Again, the Mizukoshi member intercalates three limestones, and the uppermost one of them is called “Cidaris zone”, so this limestone seems to be the geological horizon of Balanocidaris.

According to Tanaka and Okubo (1954), Enallaster yuasensis occurred from the Arita formation (Barremian: lower Cretaceous) at three points in the south between Suhara and Yoshikawa, of Yuasa-cho, Arita-gun. It is, however, presumed that Enallaster yuasensis of this paper occurred from the silty fine-grained sandstone of Toyajo formation (lower stage of Hetonaian), judging from the geological map “Todorogi” by K. Hirayama and K. Tanaka.
Fossil Echinoids

**Discription of Species**

Subclass **REGULARIA LATREILLE**

Order **Cidaroida DUNCAN**

Family **Cidaridae GRAY**

Genus **Balanocidaris LAMBERT**

*Balanocidaris* sp.

(Pl. XIV, Figs. 1-2)

All specimens are imperfect primary spines. The surface of them looks closely like to a skin of elephant. They are very thick and grandiform with rather coarse spinules.

Text-Fig. 1. Primary spine of *Balanocidaris* sp.

a : Transverse section. b : Profile.

c, d : Lateral surface like a skin of elephant.

Enallaster yuasensis TANAKA and ŌKUBO
(Pl. XIV, Fig. 3)

1954 Enallaster yuasensis TANAKA and ŌKUBO. K. TANAKA and M. ŌKUBO, On Some Echinoids from the Paleo-Cretaceous of the Yuasa District in the Kii Peninsula and of the Yatsushiro District in Kyushu, Jour. Geol. Soc. Japan, 60(705), p. 223, pl. 7, fig. 6

The test is cordiform and somewhat heart-shaped in outline. The frontal depression is not remarkable, but rather vaguely recognized.

The odd anterior ambulacrum is depressed in a shallow groove. Its poriferous zones consist of pairs of, round and slit-like pores.

All the paired ambulacra are subpetaloid. The anterior paired ambulacra are flexous, namely curve anteriorly close to the centre and turn posteriorly at the extremities. Its poriferous zones are narrower in the anterior side than in the posterior side. The pores of poriferous zones in the anterior paired ambulacra are round in the anterior side, and slit-like in the posterior side.

The posterior paired ambulacra are shorter than the anterior paired ones, and curve posteriorly. Its poriferous zones are narrower in the anterior side than in the posterior. The shape and size, of pores of poriferous zones in the posterior paired ambulacra are like very much to those of the anterior paired ones. The peristome and periproct are indistinct.
Fossil Echinoids

Length of the odd anterior ambulacrum: 25.3 mm
Width of the odd anterior ambulacrum: 5.2 mm
Length of the anterior paired ambulacra: 28.7 mm
Width of the anterior paired ambulacra: 5.0 mm
Length of the posterior paired ambulacra: 13.0 mm
Width of the posterior paired ambulacra: 4.1 mm
Angle between Amb. II and IV: 100°
Angle between Amb. II (or IV) and III: 45°
Angle between Amb. I and II (or IV and V): 90°
Angle between Amb. I and V: 100°

Geological horizon.—Toyajō formation (late Cretaceous).
Locality.—Tokuda, Yuasa-cho, Arita-gun, Wakayama Prefecture.
Matrix.—Silty fine-grained sandstone.
Collector.—Seto.

Enallaster sp.
(Pl. XIV, Figs. 4-5)

Three specimens (a, b, c) of Enallaster, sp. are being preserved in the museum. They are more or less deformed, or damaged. So the identification of species is impossible. In the specimen a, an extremity of the interambulacrum II protrudes, and the interambulacrum III is depressed. The ambulacra are indistinct except the ambulacrum III. The pores are uncertain, but the position of peristome is distinct, situated near the frontal margin of the oral side.

In the specimen b, only a frontal half of test preserves: the ambulacra II, III and IV. The oral side is indistinct.

In the specimen c, the greater part of aboral side is preserved, but the oral side is indistinct.

The above three specimens are very much like Enallaster cf. nexilis (NISIYAMA), principally in shape, although several characters of them are obscure in detail.

1948 Echinoneus cyclostomus LESKE. I. HAYASAKA, Notes on the Echinoids of Taiwan, Bull. Ocean. Inst., Taiwan, 4, p. 25, pl. 6, fig. 2
1948 Echinoneus cyclostomus LESKE. Th. MORTENSEN, A Monograph of Echinoidea, IV, Holectypoida, Cassiduloida, p. 75, pl. 1: figs. 14, 26, pl. 12: figs. 21, 23

The test is moderate in size and ovoid in shape. All the ambulacra are narrow and not invariably petaloid aborally. Each ambulacrum is the largest in width at the margin of test and tending to be narrower towards the oral side. The pore-zones of ambulacra are very narrow, slightly sunken and straight. The apical system is slightly anterior, and the posterior paired ambulacra are longer than the anterior paired ones. The genital pores are 4, lacking the posterior one. As the oral side is damaged, the peristome and periproct are indistinct.

The tubercles are imperforate or perforate, numerous, and not arranged in vertical series.
