A REVIEW OF THE JAPANESE SPECIES OF *ALCYONIUM*, 
WITH DESCRIPTIONS OF TWO NEW SPECIES AND 
AN ALMOST FORGOTTEN RARE SPECIES 
(OCTOCORALLIA, ALCYONACEA)  

Huzu UTINOMI  
2565-27, Chūoh-dai, Sirahama, Wakayama-Ken, Japan  

*With Text-figures 1–5 and Plates I–II*

**Abstract**  
Among the monomorphic genus *Alcyonium* Linné found in Japanese waters, two new species, *A. robustum* and *A. okinawanum*, are described and a longtime forgotten rare species from Sagami Bay is redescribed, newly referring to the Mediterranean species *A. acaule* Marion.  
In addition, all the previously recorded species from Japanese waters under the name of *Alcyonium* are reviewed, with the emendation of their generic status.

**Introduction**  
The monotypic genus *Alcyonium* Linné (1758) was erected for a species *A. digitatum* Linné common in the northern Atlantic seas.  
In earlier decades, this genus had often been confused with any other dimorphic genera such as *Anthomastus* Verrill, *Sarcophyton* Lesson, *Lobophytum* Marenzeller and *Sinularia* May (=*Sclerophyllum* Pratt).  
Various revisionary attempts have often been made after the comprehensive taxonomic studies by Kükenthal (1906a, b) and Lüttenschwager (1915, 1922, 1926), and some species have been transferred to other monomorphic genera such as *Metalcyonium* (Pfeffer, 1888), *Cladiella* (Gray, 1869; also known as *Lobularia* or *Microspicularia*) and *Parerythropodium* (Kükenthal, 1916).  
Concerning the more primitive monomorphic genus *Bellonella* (Gray, 1862), which was confused with *Nidalia* (Gray, 1835) by Kükenthal (1906), I already discussed nomenclaturally (Utinomi, 1957, 1958).  
Concerning the other monomorphic genus *Alcyonium* s. str. (=*Eualcyonium* Lüttschwager, 1922 pars) occurring in Japanese waters, Kükenthal (1906b) first described a new species *A. gracillimum* from the Sagami Bay off Misaki. Subsequently, Nutting (1912) mistakenly referred an apparently resembling northern specimen collected by the U.S. Fisheries steamer “Albatross” from the Okhotsk Sea to this species and also a similar specimen obtained from the west of the Sahalin Island described under the

(Article 14)
name of *A. kukenthali*, n. sp. As to their affinity see p. 201 in the following account.

Prior to this “Albatross” Cruise during 1906, Verrill (1869, p. 191) recorded a species as ‘*Alcyonium?’ in his preliminary report on the polyps and corals collected during the U. S. N. North Pacific Exploring Expedition 1853 to 1856 and Dr. Wm. Stimpson, naturalist to the expedition, with brief mentionings: “This species is as yet known only from a small and imperfect specimen. Not having had an opportunity to examine its spicula, I am unable to refer it to its proper genus. It cannot belong to *Lobularia* as defined by Dr. Gray.” (Verrill, 1869, Proc. Essex Inst., 6:46).

In all probability, however, it may be deduced that the octocorals early recorded by both Verrill and Nutting from the Sea of Okhotsk may be a boreal nephtheid, now known as *Gersemia rubiformis* (Ehrenberg), not an alcyoniid species (cf. Utinomi, 1961, pp. 232–236).

Furthermore noteworthy is the fact that the earliest record of another remarkable species of *Alcyonium* was made by a famous old zoologist, Isao Ijima, then Professor of the University of Tokyo, in his monumental standard text-book of zoology, “Dōbutsugaku Teiyō (A Manual of Zoology)” (First published in March, 1918), just 12 years later than the description of *Alcyonium gracillimum* by Kükenthal (1906) from Sagami Bay, mostly based on Haberer’s and Doflein’s collections from Sagami Bay. The details of this *Alcyonium* will be discussed in later pages.

In this connection, I tried to revise all the earlier records of octocorals originally referred to the genus *Alcyonium* from the available literature according to the recently recognized conception of the allied genera.

**Acknowledgments**

I am very much indebted to Dr. Itiro Tomiyama, then the Director of the Misaki Marine Biological Station and now of the Biological Laboratory of the Imperial Household, Tokyo, for the transference of the unobtainable specimens of *A. acaule* for detailed study and permanent preservation, and Professor Kiyoshi Yamazato of the University of Ryukyus and also to Mr. Torao Yamamoto, president of the Nanki Biological Society for the gift of specimens of new species, *A. okinawanum* and *A. robustum* respectively, both of which are now kept in the type specimen collections of the Seto Marine Biological Laboratory. My thanks are also extended to Dr. Eiji Harada of the same Laboratory and to Mr. Yoshihisa Koyama of the Gakken Publishing Co., Ltd., Tokyo for preparing fine color and monochrome photographs appeared in this paper.

The authorities of the Zoological Station of Naples, Italy have kindly sent me the well preserved specimens of the Mediterranean *Alcyonium* species (*A. acaule* and *A. palmatum*), together with *Cornularia cornucopiae* as well as a scleractinian *Astroides calycularis* for comparative study and exchanges.
A Review of Japanese Alcyonium

I. Description of *Alcyonium robustum*, sp. nov.

*Alcyonium robustum* Utinomi, sp. nov.

(Text-figs. 1–2; Plate I, figs. 1–2)

Diagnosis.—Colony rather tall, candelabrum-shaped, exceedingly robust, solid in texture and deep red either in life or in dry state; polypiferous capitulum formed of a few long, upright palmate lobes, often with short side branches and short, thick sterile stalk spreading over rocky substratum; lobes and branches digitate, uniformly round in section, uniformly covered with autozooids, arranging in longitudinal rows; anthocodiae and anthosteles elongate, armed with warty spindles or tuberculate cylinders peripherally in longitudinal rows; lacking crown rows; inner cortical layer of lobes and stalk contain numerous tuberculate spheres or short-waisted capstans, either red-colored or colorless; interior rather flaccid, only containing pink-colored less-tuberculate spheres or disc-formed spicules in fewer numbers; Living on rocky bottom of deeper depth (120–150 meters).

Holotype.—Off Minabe on the eastern coast of Kii Strait, middle Japan, depth about 120–150 meters, on a conglomerate rock-debris; 3 April, 1973. Torao Yamamoto, collector. SMBL-Type No. 249.

Coloration.—Carmine-red on the outer surface, translucent pinkish hue in fully extended polyps, when alive in aquaria kept shortly after collected by gill-nets for catching the spiny lobsters (See Plate I, fig. 2).

When dried or preserved in alcohol, it appears to be deep-red (See Plate I, fig. 1).

General appearance.—The holotype specimen is apparently candelabrumlike in the mode of growth, instead of low, fleshy, knobby form as seen in the related common species *A. gracillimum* Kükenthal (Plate I, fig. 3 in living state) and of a short arborescent or clavate form as seen in the rare species *A. cf. acaule* Marion preserved in alcohol) (Plate I, fig. 4).

It measures 80 mm in total height and 50 mm in maximum breadth. So, the colony is much larger and taller than both of the other species mentioned above, occurring in middle Japan.

Its lower stem is attached firmly to a conglomerate rock-debris partly encrusted by a bryozoan *Celleporina costazii* (Audouin), is thickened and laterally flattened, being about 30 × 15 mm in extent and about 20 mm in height where the outer surface is free from zooids.

The cortex of the lobes and basal stalk is exceedingly thick and very rigid. The polyparium consists of three erect digitate main lobes with short side branches approximately arranged in one row, arising on the flattened basal stalk, so that they may take a palmate form as a whole. These erect lobes are uniformly cylindrical up

---

2) Originally derived from the name of Sakata-Kintoki, who was a traditional hero in old Japan, as referring to its deep red coloration of body and then usually used as vernacular name for various red-colored Holocentrid fish and carrot (a kind of vegetables).
Text-fig. 1. *Alcyonium robustum*, sp. nov.

Two fully extended polyps, showing the arrangement of spicules on the surface of wall, rather schematically.

to rounded tips, measuring about 4 cm to 6 cm in length and about 1.0 cm to 1.5 cm in basal diameter. The side-branches arising either obliquely upwards or horizontally and younger lobes arising from the basal stalk are about 1.5 cm to 2 cm in length and about 4 mm to 6 mm in basal diameter.

The calyces, within which the autozooids are completely retractile, are arranged uniformly or somewhat in longitudinal rows and about 1 or 2 mm apart from each other on all sides of lobes and branches. They are low hillocks, about 0.5–0.7 mm high and 1.5 mm across in dry state.

The anthocodiae, when fully extended in life, are elongate, horn-like in appearance, up to 2 mm in length, including tentacles (Text-fig. 1; Plate I, fig. 2).

Text-fig. 2. *Alcyonium robustum*, sp. nov.

*a*, Anthocodial spicules; *b*, inner cortical spicules from sterile stalk, *c*, outer cortical spicules from surface of lobes and calyces; *d*, coenenchymal spicules from interior of lobes. (×113)
A Review of Japanese Alcyonium 195

Texture and coloration.—The cortex is exceedingly thick and very rigid in texture and deep red in color, while the interior is rather flaccid and almost colorless.

Spiculation.—In the inner layer of the cortex of the sterile stalk and polyipiferous lobes there are numerous tuberculate spheres or short-waisted capstans, about 0.08 to 0.12 mm long, either red-colored or colorless (Text-fig. 2, b), while the surface layer contains slender spindles and larger tuberculate cylinders (with large warts more or less girdled), about 0.1 mm to 0.22 mm long, mostly red-colored (Text-fig. 2, c).

The coenenchymal spicules in the interior of lobes are mostly less-tuberculate spheres or indistinctly waisted capstans or smaller disc-formed ones, about 0.05-0.12 mm, mostly pink-colored to colorless (Text-fig. 2, d).

The anthocodial spicules are arranged apparently not en chevron but longitudinally, and lack crown rows below. These point spicules are all smooth needles or slender spindles with minute warts, about 0.1-0.12 mm long, vividly red-colored (Text-fig. 2, a).

Remarks.—In the mode of branching and the arrangement of zooids on the surface of the lobes and branches, this new species most resembles A. glomeratum Hassal (e. g. Hickson, 1895, pl. 36, fig. 2) and A. acaule Marion (e. g. Verseveldt, 1964, pl. XI, figs. 1-6). However, its largeness in size and rigidity verify it a valid species distinct from both of Alcyonium species hitherto known from the northern Atlantic.

For differentiating from the common Japanese species A. gracillimum Kükenthal (e. g. Kükenthal, 1906b, pl. I, fig. 3 and the present paper, pl. I, fig. 3), I recapitulate the main characters of both species in the following table.

<table>
<thead>
<tr>
<th>A. gracillimum K.</th>
<th>A. robustum sp. nov.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Colony small, low, irregularly 5-10 cm in height, rather soft and flaccid.</td>
<td>1. Colony much larger, palmate, 8 cm in height, 5 cm wide in the type, very rigid.</td>
</tr>
<tr>
<td>2. Polypiferous lobes obscurely delimited from sterile stalk.</td>
<td>2. Polypiferous lobes distinctly delimited from sterile stalk.</td>
</tr>
<tr>
<td>3. Lobes rather low, knobby and transversely wrinkled.</td>
<td>3. Lobes long, digitate and arranged in one row, obscurely furrowed longitudinally.</td>
</tr>
<tr>
<td>4. Zooids irregularly arranged as knobby mass on whole branches. Only a few zooids placed solitarily on surface of lobes or stem.</td>
<td>4. Zooids longitudinally arranged with intervals of 1-1.5 mm.</td>
</tr>
<tr>
<td>5. Colony usually orange-colored.</td>
<td>5. Colony usually deep red.</td>
</tr>
<tr>
<td>6. Anthocodiae low conical, about 2.5 mm long and 2 mm wide, with chevroned point spicules (much warty spindles) and 3-4 rows of crown spicules.</td>
<td>6. Anthocodiae elongate horn-like in form, with smooth or less warty point spicules longitudinally arranged, lacking crown spicules.</td>
</tr>
<tr>
<td>7. Outer layer of stem and lobes thin, contains blunt-ended spindles, mostly 0.15-0.3 mm long.</td>
<td>7. Cortex of lobes and stalk very thick, composed of two layers. Its outer layer contains slender spindles and tuberculate cylinders about 0.1-0.22 mm long and inner layer contains warty spheres or capstans, about 0.05-0.12 mm long.</td>
</tr>
<tr>
<td>8. Coenenchymal spicules are large, plump spindles with compound warts, up to 1 mm long, mostly colorless.</td>
<td>8. Coenenchymal spicules are small, less-warty spheres or discs, about 0.05-0.12 mm, mostly pink-colored.</td>
</tr>
</tbody>
</table>
II. Description of *Alcyonium okinawanum*, sp. nov.

*Alcyonium okinawanum* Utinomi, sp. nov.

(Text-fig. 3; Plate II, figs. 5–6)

Diagnosis.—Colony very flaccid, consisting of membranous basal stalk and irregularly ramified flexible lobes densely covered with papillate autozooids; greenish brown in life; fully extended anthocodiae with 7–13 pairs of digitate pinnules devoid of spicules; coenenchymal spicules in both surface and interior mostly minute smooth rodlets about 0.2–0.3 mm long; living on shallow-water coral reef of Okinawa Island.

Holotype.—Nagusuku coast of Itoman-cho, southwest of Okinawa-jima, Ryukyu Archipelago, depth not mentioned but possibly on mean sea-level. 5 April, 1962. Kiyoshi Yamazato, collector. SMBL-Type No. 268.

General appearance.—The holotype specimen is preserved in alcohol, so that

Text-fig. 3. *Alcyonium okinawanum*, sp. nov.

a, Distal part of fully stretched lobes slightly branched; b, 3 fully extended tentacles, showing varied length of pinnules; c, cortical spicules from outer layer of sterile stalk; d, coenenchymal spicules from canal-walls of lobes.

(Scales a and b respectively apply to adjacent figures. The scale at the bottom only applies to Figs. c and d.)
it may be somewhat contracted. It measures 5–6 cm in total height, with maximum expanse of about 5 cm.

The sterile stalk is very short and flattened, spreading over a dead coral block. Its basal diameter is 2 cm × 4 cm intact. It widens upwards and passes into the polyparium, which consists of 4 primary lobes, and then gives off a few shorter branches. The distal part of the main lobes and branches (Text-fig. 3, a) are all digitate in form, uniformly cylindrical to elongate conical, being about 10–20 mm long and 5–10 mm wide, directing upwards or obliquely upwards. They are all flabby in texture and olive buff in color.

Around these lobes many papillate autozooids are densely distributed, decreasing to the distal ends. Each zooid is about 1.5 mm wide and slightly longer, sometimes with fully extended tentacles clearly detectable.

The fully expanded anthocodiae have 8 fimbriate tentacles, about 2 mm long. Usually, the pinnules are of 10–13 pairs and their proximal 2 pairs are much longer up to 0.5 mm long, while the distal ones may be one-half in length or obsolete (Text-fig. 3, b).

Spiculation.—The anthocodiae, including tentacles, lack spicules.

The spicules contained in both the surface layer and canal-walls of lobes are predominantly smooth tiny rods, measuring about 0.03–0.15 mm in length, but extraordinarily large, similar-shaped, smooth rods (3 × 0.5 mm) are occasionally found (Text-fig. 3, c–d).

Remarks.—The external appearance and flabby texture of this specimen remind of *A. aspiculatum* Tixier-Durivault from Australia (Tixier-Durivault, 1966a, p. 706, fig. 1) and *A. flaccidum* Tixier-Durivault from Madagascar (Tixier-Durivault, 1966b, p. 29, figs. 10–11; Verseveldt, 1971, p. 5, pl. I, fig. 1).

However, the spiculation mentioned above seems to be related to that of *A. utinomii* Verseveldt (1971, p. 7, fig. 3) from Madagascar, but the absence of such spicules as sharply ended spindles and hexagonal discs, characteristic to the latter species, deserves to establish a new species for the present specimen from Okinawa, as distinct from both species.

Although morphologically different, these recently found *Alcyonium*-species may belong to the same group, because of the occurrence on the shallow-water coral reef and of the dull coloration probably due to the close association of zooxanthellae or zoochlorella in the coenenchyme.

III. Redescription of Ijima's 'Alcyonium sp.', Referable to *Alcyonium acaule* Marion

*Alcyonium cf. acaule* Marion

Nom. Jap.: Hime-umitosaka (Utinomi, 1974)

(Text-figs. 4–5; Plate I, fig. 4)

History of material.—Famous Japanese grand zoologist Isao Ijima, then Professor
of the Imperial University of Tokyo, gave a fine figure of an arborescent form of *Alcyonium* obtained from Sagami Bay, together with its spicules in his monumental textbook “Dōbutsugaku Teiyō” (1918, Tokyo, p. 326, fig. 374).

Material examined.—Five specimens (from 7 mm to 40 mm in total length) and 2 younger fragments.

These valuable specimens, probably collected by Kumakichi Aoki, a well-known collector at the Misaki Marine Biological Station, from off Misaki where the Station is placed, in his life time.

Unfortunately its collecting data and occurring depth are unknown at present.

These specimens had been deposited at the specimens-depositing room in that Station for many years before 1951, and afterwards transferred to the Museum of the Seto Marine Biological Laboratory of Kyoto University, and then permanently deposited, registering as SMBL-Rare No. 268.

A colony represented by the aforementioned Ijima’s figure seems to correspond with largest one retained at present (See Text-fig. 4, a and Plate I, fig. 4).

Redescription of these specimens forgotten and neglected for many years and hitherto never found again from anywhere in Japanese waters. Among the specimens examined here, the largest one is a branched arborescent colony, about 4 cm

---

Text-fig. 4. *Alcyonium cf. acaule* Marion. (SMBL-Rare No. 268).

a, Largest branched specimen (the same as Pl. I, fig. 4); b, smaller unbranched specimen. (×1.6)

3) Presumably, this figure of total form and contained spicules might had been made originally by his pupil Kumao Kinoshita, the late distinguished specialist on Octocorallia.
A Review of Japanese Alcyonium

in height and 10 mm x 15 mm in extent of the base, detached from the substratum.

The polyparium consists of 4 erect, club-shaped lobes, about 10-20 mm long and terminally about 5-8 mm wide. The sterile stalk is about 10 mm long, so approximately less than one-half of the total height, and longitudinally furrowed or wrinkled, probably due to a longtime preservation. In addition, a young daughter colony (about 10 mm long and 3 mm wide) is arisen from the side of the basal disc. The remaining smaller colonies (Text-fig. 4, b) are unbranched, consisting of a clavate polyparium and a slender short sterile stalk, measuring 1 cm, 2 cm and 2.5 cm in height respectively.

They are uniformly dark wine-red in color, although the partly extended large polyps are slightly paler.

The autozooid (Text-fig. 5, a), when partly extended, is large, about 3-5 mm

Text-fig. 5. *Alcyonium cf. acaule* Marion.

a, Well-grown polyp, showing the arrangement of spicules; b, anthocodial point spicules; c, spicules from neck zone; d, spicules from stalk cortex; e, spicules from calyx wall; f, spicules from canal-walls of sterile stalk.

(a, ×20; b-e, ×80; d-f, ×230)
long, excluding tentacles withdrawn and bear 8 rows of steeply converging slender fusiform spicules on the surface of the head portion, below these similar spicules are arranged in transverse rows, not forming distinct crowns, and in the lower neck portion there are smaller warty rods loosely arranged in transverse rows, becoming more densely and irregularly basalwards.

Fully grown tentacles bear about 12 long pinnules on each side in the lower half of the length.

Spiculation.—The anthocodial spicules are scarcely warty spindles sharply pointed on both ends, about 0.17–0.44 mm long and 0.018 mm wide (Text-fig. 5, b). The anthostellar neck zone bears warty rods, about 0.05–0.018 mm long and 0.026 mm wide (Text-fig. 5, c). The cortical spicules in the sterile stalk are slightly longer, similar warty spindles with high warts sometimes girdled and the color varies from colorless to red (Text-fig. 5, d). Those from the calyx wall are high-warted spindles or club-like rods, about 0.06–0.18 mm long (Text-fig. 5, e). The coenenchymal spicules thickly filled in the canal-walls are more larger warty spindles, red-colored, about 0.08–0.2 mm long and 0.05 mm wide (Text-fig. 5, f).

Consideration on its affinity.—In looking at this old material which I have not ever encountered in Japanese waters, it struck me that the specimens, either branched or unbranched, still retain dark wine-red coloration and very like the figures or photographs of Alcyonium acaule Marion (1878), which has hitherto been believed to be endemic to the Mediterranean Sea, and also Pütter’s figure of Ammnothea rubriflora recorded only once from unknown locality (probably China Sea ?, after his original note) (cf. Pütter, 1900, p. 451, pl. 39, figs. 3 and 10). Accordingly, I compared it with the typotypic specimens of A. acaule and A. palmatum which had been sent to me from the Zoologi-Station of Naples, Italy (unbranched colony of the former, SMBL-Rare No. 225; branched colony of the latter, SMBL-Rare No. 224), and at the same time consulted available literatures (Koch, 1891; Studer, 1901; Kükenthal, 1907; J.A. Thomson, 1927; Verseveldt, 1964). As a result, I conclude herein that the specimens here concerned is certainly identified with A. acaule Marion.

So, the alleged names such as Ammnothea rubriflora Pütter (1900) and Alcyonium brinoniense Kükenthal (1907), are to be discarded as junior synonyms of Alcyonium acaule Marion (1878).

In connection with this, it is not surprising that the ‘Mediterranean’ species such as this A. acaule does occur in the West Pacific, especially in the far easternmost Sagami Bay, too, As mentioned by Ekman (1953, p. 87): “Several of the Miditerranean warm-water animals have been regarded as relicts from the Tertiary Tethys Sea.”, indeed there is faunistically a close relationship between the Sagami Bay and the Mediterranean Sea as far as the Octocorallia is concerned, for example the cases of Paralcyonium elegans M. Edw., Daniela koreni v. Koch (=Cereopsis studeri v. Koch) and Bebryce mollis Phil. recorded first from the Mediterranean (cf. e.g. Thomson and Dean, 1931; Stiasny, 1941; Utinomi, 1960; unpublished data).
