Abstract: The basic-helix-loop-helix transcription factors *Ascl1*/*Mash1*, *Hes1*, and *Olig2* regulate fate choice of neurons, astrocytes, and oligodendrocytes, respectively. These same factors are coexpressed by neural progenitor cells. Here, we found by time-lapse imaging that these factors are expressed in an oscillatory manner by mouse neural progenitor cells. In each differentiation lineage, one of the factors becomes dominant. We used optogenetics to control expression of *Ascl1*, and found that although sustained *Ascl1* expression promotes neuronal fate determination, oscillatory *Ascl1* expression maintains proliferating neural progenitor cells. Thus, the multipotent state correlates with oscillatory expression of several fate-determination factors, whereas the differentiated state correlates with sustained expression of a single factor.

Word limit includes text + references + figure and table legends

Main Text: Analyses of populations of mouse hematopoietic progenitors suggest that general fluctuations in the transcriptome affect lineage choice (1). On the other hand, analyses of individual cells do not show an effect of transcriptome fluctuation on lineage choice (2). Fate choice could be a gradual process based on transcriptome-wide fluctuations or discrete processes through different subpopulation states. To address these issues, we study the expression patterns of fate determination factors in individual mouse cells in the multipotent state and during fate choice processes.

In the developing murine nervous system, neural progenitor cells (NPCs) proliferate (reproducing themselves) and also differentiate into three cell types, neurons, oligodendrocytes, and astrocytes (thus demonstrating multipotency). Transcription factors that regulate the proliferation of NPCs and the differentiation of each cell type include basic helix-loop-helix (bHLH) transcription factors (3,4). For example, proneural bHLH genes such as *Ascl1/Mash1* and *Neurogenin2 (Ngn2)* promote neuronal fate determination and suppress astrocytic gene expression (5-7). The bHLH gene *Olig2* regulates oligodendrocyte specification, while the bHLH genes *Hes1* and *Hes5* maintain NPCs by repressing proneural gene expression (8-12). *Ascl1* and *Olig2* also regulate oligodendrocyte and motor neuron development, respectively (8-10,13-18). One model suggests that *Hes* genes, expressed by NPCs, repress expression of other bHLH genes; down-regulation of *Hes* genes allows up-regulation of proneural genes or *Olig2* and subsequent differentiation into neurons or oligodendrocytes (4). However, *Ascl1* is expressed by dividing NPCs and postmitotic neurons, and *Ascl1* up-regulates the expression of genes involved in cell cycle progression of NPCs as well as in cell cycle exit and neuronal differentiation (19,20). Furthermore, *Hes1* promotes the maintenance of NPCs and astrocyte differentiation (11,12,21,22). *Olig2* is also involved in NPC proliferation (23). Thus, these bHLH genes exert contradictory functions.

Hes1 expression oscillates with a period of approximately 2-3 hours in many cell types including NPCs (24,25). *Ngn2* expression also oscillates in NPCs probably because it is periodically repressed by *Hes1* oscillation. In differentiating neurons, which lack *Hes1* expression, *Ngn2* expression is steady (25). Thus, the pattern of bHLH gene expression differs between NPCs and neurons, although our previous time-lapse imaging study only monitored mRNA production (25). As transcription and translation can be dissociated (26), we here study protein expression at the single cell level. We found that *Hes1*, *Ascl1*, and *Olig2* protein expression oscillates in NPCs.

Variable levels of bHLH transcription factor expression in NPCs

Ascl1, *Hes1*, and *Olig2* are expressed by NPCs in the ventral telencephalon, which generate neurons, astrocytes, and oligodendrocytes during perinatal stages of mouse development (14-18,27,28). The expression levels of these transcription factors were variable from cell to cell (Fig. 1A-H). Many cells were positive for all three bHLH factors (*Hes1*, *Ascl1*, and *Olig2*), while others expressed only two (Fig. 1E-H). By contrast, differentiating neurons, oligodendrocytes, and astrocytes expressed only one of them at later stages (i.e., *Ascl1*, *Olig2*, and *Hes1*, respectively) (18,22,29). To examine the expression of these bHLH factors, we generated transgenic mice carrying reporters in which fluorescent (Venus or mCherry) or firefly luciferase (*Luc2*) cDNA was inserted in frame into the 5' region of each bHLH gene in BAC clones so that a bHLH factor fused with either Venus, mCherry, or *Luc2* was expressed (table S1, fig. S1A-F). We also generated knock-in mice in which Venus was inserted in frame into the 5' region of the *Hes1* gene for *Hes1* imaging (table S1, fig. S2A), those in which Venus or luciferase (*Eluc*) was

inserted in frame into the 5' region of the *Hes5* gene for Hes5 imaging (table S1, fig. S2B,C), and Sox2 reporter mice expressing a Luc2-Sox2 fusion protein (table S1, fig. S1G). The reporter expression in these mice was similar to endogenous expression (fig. S3). Reporter expression also correlated well with endogenous protein expression in NPCs (fig. S4). The brain structures and the NPC competency of these reporter mice including homozygous Venus-Hes1 fusion knock-in mice were apparently normal (fig. S5).

We used time-lapse imaging of brain slices from the ventral telencephalon of reporter mice and found that Hes1 and Ascl1 expression oscillate in NPCs (Fig. 1I-K, movie S1).

Oscillatory expression of bHLH factors in NPCs

We next prepared NPCs from the ventral telencephalon of perinatal reporter mice. We used acutely dissociated NPCs and those maintained *in vitro* for at least ten generations in the presence of EGF and bFGF (NS cells)(30,31). Both cell types exhibited similar expression oscillations in the progenitor state and during cell fate choice. These NPCs express Ascl1, Olig2, and Hes1 at variable levels (fig. S6) and generate GABAergic neurons, oligodendrocytes, and astrocytes (fig. S7, (14)). Their competency to generate neurons and oligodendrocytes was significantly reduced in the absence of Ascl1 and Olig2, respectively (fig. S7G,H',I,K). These NPCs also showed a reduced ability to generate astrocytes in the absence of Hes1 (fig. S7F',J). Compared to the bHLH factors, the NPC-specific factor Sox2 (32) was expressed at a relatively constant level (fig. S6A,E,J).

We used time-lapse imaging to analyze expression patterns of bHLH factors. Hes1 protein expression oscillated in NPCs (average period 149.9 ± 12.3 min)(Fig. 2A,D,G,H, fig. S8, movie S2). Hes5 expression in NPCs oscillated in phase with Hes1 expression (figs. S9 and S10). Ascl1 expression oscillated in NPCs (average period 175.4 ± 29.5 min)(Fig. 2B,E,G,I, fig. S11, movie S3). The Ascl1 protein level was up-regulated during S/G2 in some cells (~30%, fig. S11C,D); after cell division both daughter cells showed equal amounts of Ascl1, and expression oscillations resumed in cells that remained undifferentiated (fig. S11D). Olig2 protein expression also oscillated, but more slowly (average period 375.5 ± 105.8 min) than Hes1 and Ascl1 protein oscillations (Fig. 2C,F,G, fig. S12, movie S4). The average expression levels of these factors are different between G1 and S/G2/M (fig. S13), although their expression oscillated throughout the cell cycle. By contrast, two other factors characteristic of NPCs were expressed steadily: Sox2 and Nestin (figs. S13C and S14, movie S5). Hes1 and Ascl1 expression are inversely correlated (fig. S15A,D, (33)); Hes1 represses Ascl1 expression by binding to the *Ascl1* promoter (34). Oscillating Hes1 would periodically repress Ascl1 expression, thereby driving oscillations in Ascl1 expression. Indeed, oscillatory Ascl1 expression was lost in the absence of Hes1 (fig. S11E,F). Expression of Olig2, on the other hand, changes independently of Ascl1 and Hes1 (fig. S15B,C,E,F).

We next examined whether the oscillations in bHLH factor expression levels create a bias in differentiation competency. We separated NPCs of the fluorescent reporter mice into Hes1-high, Hes1-low, Ascl1-high, Ascl1-low, Olig2-high, and Olig2-low fractions (fig. S16A-C). All cell fractions kept in NS media returned to original diverse levels of Hes1, Ascl1, and Olig2 expression within 2 days, suggesting that diverse levels represent different phases of expression oscillation (fig. S16D-L). All cells generated neurospheres at similar efficiencies (fig. S16M-R). After sorting, each cell population was cultured in a differentiation medium. Hes1-high and Hes1-low cells preferentially differentiated into astrocytes and neurons, respectively (fig. S17A,B). Ascl1-high (and Olig2-low) and Olig2-high (and Ascl1-low) cells preferentially

differentiated into neurons and oligodendrocytes, respectively (fig. S17A,C-G). These results suggest that the different expression levels of the bHLH factors bias the fate choice of NPCs. However, such transient high expression is neither required nor sufficient for cell fate determination: NPCs with high expression of any of *Ascl1*, *Olig2*, and *Hes1* were all able to differentiate into any of the three cell types (fig. S17).

Sustained expression of bHLH factors during cell fate choice

We next examined how the expression of these bHLH factors changes during cell fate choice. During neuronal differentiation, *Ascl1* protein accumulated after cell division (Fig. 3A-D), in contrast to oscillatory expression in NPCs, and 6-8 hours later, the early neuronal marker Doublecortin (DCX) was expressed (Fig. 3A,C-D'). *Ascl1* expression continued to be up-regulated in many cells (76.7%, Fig. 3A-C) but not in others (23.3%, Fig. 3D) after DCX expression was initiated, raising the possibility that the minimum requirement for neuronal differentiation is accumulation of *Ascl1* over 6 to 8 hours during G1.

In acute dissociation culture from the ventral telencephalon, many NPCs underwent asymmetric cell division in which one daughter cell remained undifferentiated while the other differentiated into a neuron. In these NPCs, *Ascl1* expression was up-regulated (at least two-fold compared to the average) before cell division and seemed to be equally distributed in both daughter cells (Fig. 3E). In the daughter neuron, *Ascl1* expression accumulated after cell division, while it resumed oscillating in the daughter NPC (Fig. 3E). Before neurogenic cell division (one or both daughter cells underwent neuronal differentiation), *Ascl1* expression was transiently up-regulated (at least two-fold compared to the average) in many cases: ~90% of their mother cells exhibited such transient up-regulation of *Ascl1* before cell division (fig. S18B). However, ~30% of mother cells did so when they produced two daughter NPCs (figs. S11C,D and S18B). Thus, the transient up-regulation of *Ascl1* before cell division is not decisive, but merely lends a bias toward neuronal fate choice.

In those NPCs whose daughter cells underwent neuronal differentiation, *Hes1* expression was repressed before cell division (Fig. 3E', fig. S18A,E,F) but not when both cells remained NPCs (fig. S18A,C,D). The suppression of *Hes1* expression was maintained in daughter neurons (Fig. 3E', fig. S18E,F), while *Hes1* oscillation resumed in daughter NPCs (Fig. 3E'). Thus, it is likely that transient down-regulation of *Hes1* expression and the concomitant up-regulation of *Ascl1* before cell division directs NPCs toward neuronal fate choice, and that sustained expression of *Ascl1* after cell division irreversibly determines neuronal fate. Down-regulation of *Hes1* could be caused by fluctuations of the expression levels of Notch intracellular domain (NICD), an active form of Notch signaling (35)(fig. S19). Indeed, when stable NICD expression was induced from the *Rosa26* locus in NPCs, both *Hes1* and *Hes5* expression oscillated sustainably, and there was no down-regulation of these factors (figs. S20 and S21). By contrast, in the presence of a γ -secretase inhibitor, which inhibits Notch signaling activity, *Ascl1* and *Olig2* expression was up-regulated to stable expression (fig. S22).

During astrocyte differentiation, *Hes1* protein expression still oscillated but at high average and trough levels (Fig. 4A,B, fig. S23B,C). 12-24 hours later, expression of the astrocyte marker GFAP began (fig. S23A). *Ascl1* and *Olig2* expression became undetectable within 10 hours during astrocyte differentiation (fig. S23D-G). During oligodendrocyte differentiation, *Olig2* protein expression oscillated, but at high trough levels (Fig. 4C,D, fig. S24A,C,E). A few days after induction of oligodendrocyte differentiation, *Olig2* expression was down-regulated, and expression of the mature oligodendrocyte marker 2',3'-Cyclic-nucleotide-3'-

phosphodiesterase (CNPase)(fig. S25) was up-regulated (Fig. 4E, fig. S24B,D,G). During this period, *Ascl1* and *Hes1* expression were down-regulated (fig. S24H-J). Thus, bHLH fate determination factors are coexpressed in an oscillatory manner in NPCs, but as the cell fate choice becomes established, one factor accumulates and the other two are lost. Although oscillatory expression of multiple fate determination factors underlies the multipotent state of NPCs, this oscillatory pattern gives way to stable and dominant expression of one factor during cellular differentiation.

Light-induced control of expression pattern

To demonstrate the functional importance of oscillatory or sustained expression patterns, we adopted the optogenetic gene expression system using the *Neurospora crassa* photoreceptor Vivid that was fused with Gal4 DNA-binding domain and p65 activation domain (GAVPO)(36). The codon usage was optimized for mammalian cells to increase expression efficiency, and the target mRNA was destabilized by introducing the 3'-untranslated region of mouse *Ascl1* mRNA (fig. S26A). With this system, we can induce gene expression comparable to endogenous levels (fig. S26D-G). Repeated exposure of blue light with 3-hour intervals generated oscillatory expression with a 3-hour period, while repeated exposure with 30-min intervals generated sustained expression at both cell population (Fig. 5A) and single cell levels (Fig. 5B,C, movie S6).

Because *Ascl1* is known to promote the cell cycle progression of NPCs and their cell cycle exit and neuronal differentiation (20), we asked whether these contradictory functions of *Ascl1* are regulated by different expression patterns. We introduced the *Ascl1*-inducible system into *Ascl1*-null NS cells, which produce no neurons (fig. S7) and proliferate more slowly than wild-type NS cells (20). *Ascl1*-null NS cells have a low proportion (4-5%; PH3⁺) of dividing cells (Fig. 5E), while wild-type NS cells have 14-15% PH3⁺ dividing cells (see Fig S29C). However, light-induced oscillatory expression of *Ascl1* increased the proportion of dividing cells in the *Ascl1*-null NS cell population to ~10% PH3⁺ (Fig. 5E-G), suggesting that *Ascl1* oscillation enhanced NPC proliferation. These NS cells did not differentiate into neurons (β III-tubulin⁺) even after 3 days (Fig. 5D). The period of this oscillation is important, because a 6-hour period did not affect NPC proliferation (fig. S27). By contrast, light-induced sustained expression of *Ascl1* enhanced neuronal differentiation (β III-tubulin⁺) of *Ascl1*-null NS cells (Fig. 5H-K). A higher level of sustained *Ascl1* expression increased the efficiency of neuronal differentiation (Compare Fig. 5H versus fig. S28E). However, oscillatory *Ascl1* expression did not induce neuronal differentiation even at a higher amplitude (fig. S28A-C) but increased the number of proliferating NPCs (fig. S28D). By contrast, sustained *Ascl1* expression at similar levels increased neuronal differentiation (fig. S28E). These results indicate that distinct expression patterns, but not the levels, of *Ascl1* are important for a choice between proliferation and differentiation.

We used the *Ascl1*-inducible system in wild-type NS cells where endogenous *Ascl1* expression oscillates (fig. S29). Oscillatory light stimulation with 3-hour intervals did not affect the neurogenesis or proliferation of these cells (figs. S29A-I and S30A-D). By contrast, sustained *Ascl1* expression for 72 hours increased neuronal formation even in the presence of bFGF and EGF, a condition that inhibits neurogenesis (figs. S29J-Q and S30E). At least 6-to-8 hours of sustained *Ascl1* expression was required for generation of neurons (Fig. 5L-P), agreeing with the above notion about the minimal requirement for neuronal differentiation. This requirement for elapsed time suggests that only NS cells that caught at early G1 could be redirected by light-

induced expression of *Ascl1* into neuronal development. The *Ascl1*-inducible system was also introduced into the dorsal telencephalon, which normally expresses very low levels of *Ascl1*. The oscillatory expression of *Ascl1* did not induce neuronal differentiation but did maintain Nestin⁺ NPCs in the ventricular zone, while the sustained expression of *Ascl1* increased the number of β III-tubulin⁺ neurons that migrated out of the ventricular zone (fig. S31). Thus, manipulation of *Ascl1* gene expression can impose a choice favoring proliferation or differentiation according to whether the *Ascl1* expression is oscillatory or sustained.

Discussion

Our data suggest that multipotency is a state of multiple oscillating neurogenic and gliogenic determination factors, and that cell fate choice is a process of sustained expression of a single factor. This switching may be induced by the fluctuations of Notch signaling (Supplementary Text). The detailed mechanism by which the oscillatory and sustained *Ascl1* expression differentially regulates downstream gene expression remains to be determined. It was reported that the proneural factor *Ngn2* is differentially phosphorylated between NPCs and neurons and controls the expression of its target genes differently depending on its phosphorylation status (37). We speculate that the oscillatory and sustained expression of proneural factors could be involved in different posttranscriptional modulation that is responsible for target gene selectivity. We also demonstrated that the light-switchable gene expression system offers a new way to control the proliferation and differentiation of stem cells by changing the light exposure pattern rather than using different growth factors or chemicals, showing its applicability to the regeneration technology.

FIGURES

Fig. 1. Variable expression levels of bHLH factors in NPCs of the ventral telencephalon. (A-H) The expression of Hes1, Ascl1, and Olig2 in the ventral telencephalon at perinatal stages was examined by immunohistochemistry. The boxed region in (D) is enlarged in (E-H). Many cells were positive for all three bHLH factors (Hes1, Ascl1 and Olig2, arrowheads), while others were mostly positive for two of them. (I-K) Bioluminescence imaging and quantification of Luc2-Hes1 (I,J) and Luc2-Ascl1 (K) expression in slice cultures of the ventral telencephalon of reporter mice. Scale bars, 50 μ m (A-D,I).

Fig. 2. Oscillatory expression of bHLH factors in self-renewing NPCs derived from the ventral telencephalon. (A-F) Bioluminescence images and quantification of Luc2-Hes1 (A,D), Luc2-Ascl1 (B,E), and Luc2-Olig2 (C,F) reporter expression. (G-I) The distribution of the oscillation periods of Hes1, Ascl1, and Olig2 derived from bioluminescence measurements ($n > 25$ NPCs for each factor).

Fig. 3. Sustained Ascl1 expression in differentiating neurons. Bioluminescence images of Luc2-Ascl1 (A,B,C,D,E) and Luc2-Hes1 (E') expression were quantified. (A,C,C',D,D') Ascl1 expression accumulated in differentiating neurons (A, green line; C,D, orange double asterisks). The early neuronal marker Doublecortin (Dcx) was monitored by DCX-DsRed. Transient up-regulation of Ascl1 expression occurred before cell division (C,D, magenta asterisks). (B) Temporal trajectories of Luc2-Ascl1 in NS cells just after NPC or neurogenic division at time = 0 (mean in solid line, and standard errors in colored, $n > 19$ for each division). Division-mode effect, $p = 0.0022$; interaction between division-mode and time, $p < 0.0001$, repeated measures ANOVA. (E) This acutely dissociated NPC underwent asymmetric cell division. Ascl1 was equally distributed in both daughter cells after the first cell division. Ascl1 expression accumulated in a daughter neuron (green) but resumed oscillating in a daughter NPC (red), which underwent the second division. (E') Hes1 expression was repressed before asymmetric cell division (asterisks). The suppression of Hes1 expression was maintained in a daughter neuron (blue line), whereas Hes1 oscillation resumed in a daughter NPC (red line).

Astrocyte specification was induced at time = 0 by LIF and BMP4. (C-E) Bioluminescence imaging (C) and quantification (D) of Luc2-Olig2 expression and quantification of pCNP-Venus (E) in a single cell during oligodendrocyte differentiation, which was induced by T3 at time = 0.

Fig. 5. Light-induced oscillatory/sustained expression of Ascl1 in NPCs. (A-C) Time-lapse imaging (C) and quantification (A,B) of gene expression at cell population (A) and single cell levels (B,C) induced by blue light. (D-K) According to the schedule of light exposure (fig. S26B; light intensity: 1.11 μ mol/m²/s), oscillatory (D-G) and sustained (H-K) Ascl1 expression was induced in *Ascl1*-null NPCs, which were cultured in the presence of bFGF and EGF, a condition that inhibits neurogenesis. Oscillatory Ascl1 expression induced virtually no β III-tubulin⁺ neuron formation (D) but significantly increased the proportion of dividing cells (PH3⁺), compared to the control (Ub-luc2) (E-G). Sustained Ascl1 expression significantly increased

β III-tubulin⁺ neuron formation, compared to the control (Ub-luc2) (**H,J,K**). * p <0.05, ** p <0.01; two-tailed Student's t -test. (**L-P**) According to the schedule of light exposure (fig. S26C), sustained *Ascl1* expression was induced in NPCs for indicated time lengths, and neuronal formation was examined. * p <0.05, ** p <0.01, *** p <0.001, one-way ANOVA followed by Tukey post hoc test. Scale bars, 12.5 μ m (**F,G,J,K**); 12.5 μ m (**M-P**).

Materials and Methods

Plasmid construction

To analyze the promoter activity, the ubiquitinated luciferase (Ub-luc) was used as a reporter, as previously described (38,39). This luciferase was fused at its N-terminus to one copy of a mutant ubiquitin (G76V) that resists cleavage by ubiquitin hydrolases. The resultant Ub-Luc is extremely unstable with a half-life of less than 10 min (38,39). The optimized *firefly* luciferase luc2 (Promega) was used for most Ub-luc constructs. For two-color simultaneous imaging of two promoter activities in single cells, Eluc from *Pyrearinus termitilluminans* (TOYOBO) and Red luc from *Phrixothrix hirtus* (TOYOBO) were used. For easier single-cell tracking, four copies of nuclear localization signal (NLS) of SV40 large T-antigen were attached to Ub-luc. This NLS-Ub-Luc coding sequence was inserted into the reporter constructs that contain the 5'-flanking sequences and the downstream sequences including the 3'-UTR regions.

For the Hes5 reporter construct, 3-kb of the 5'-flanking sequence and 2-kb of downstream sequence were used. For the Rosa26 reporter construct, 0.8-kb of the 5'-flanking sequence of the Rosa26 locus and SV40 late poly-A adenylation sequence were used. For the Nestin reporter construct, the 5.8-kb promoter and second intron enhancer sequence of *Nestin*, and SV40 late poly-A adenylation sequence were used. For the RBPjk-activity reporter construct, four tandem copies of the RBPjk-binding consensus sequence were placed upstream of the SV40 basal promoter, and 0.5-kb of downstream sequence of the Hes1 gene was placed downstream of Ub-luc.

In the pCNP-Venus construct, gap-Venus-T2A-Venus coding sequence was subcloned into the CNP expression cassette, which has a 3.9-kb fragment of the promoter region of CNP (2',3'-Cyclic-nucleotide 3'-phosphodiesterase) gene, and poly-adenylation sequence of SV40. The detailed cloning strategy and complete sequence of the plasmids are available on request.

Animals

All animals were handled in accordance with the Kyoto University 'Guide for the Care and Use of Laboratory Animals'. Time-pregnant females were maintained in a 12 hr light/dark cycle and obtained by overnight breeding with males of the same strain. Noon following breeding is considered as E0.5. Rosa26-LoxP-Stop-LoxP-NICD (40), DCX-DsRed (41), pCAG-mAG-hGem(1/110) (42), and pCAG-mKO2-hCdt1(30/120) (42) lines were described previously. Transgenic (Tg) or knock-in reporter strains were generated as described below.

Conventional Tg mice

To prepare the DNA fragments for pronuclear injection, the vector backbone sequences were removed. The constructs were isolated by agarose gel electrophoresis, purified with QIAEX II (Qiagen) and injected into the pronuclei of fertilized one-cell eggs from ICR mice. Typically 200-300 fertilized eggs were injected. Genotypes were determined by PCR of tail DNA.

BAC Tg mice

BAC targeting was conducted using BAC recombineering (43,44). BAC clones were selected from the Ensembl database (<http://www.ensembl.org>), and obtained from the BACPAC Resources Center at Children's Hospital Oakland Research Institute (CHORI). BAC DNA was transferred from DH10B strain to SW105 strain by electroporation. The identity and integrity of these BAC clones were verified by a panel of PCR primers and restriction digestions. For generating N-terminal reporter-fusion BAC Tg constructs, reporter coding sequences without stop codon were amplified by PCR, and cloned into pBluescript II SK+ plasmid. HA and flag epitope tags were attached to the N-terminus of Luc2 and Venus, respectively. In front of the reporter coding sequences, frt-PGK-EM7-Neo-frt cassette was inserted. The Neo gene is driven by both the PGK promoter for G418 selection in ES cells and the EM7 promoter for Kan selection in *Escherichia coli*. A BAC targeting vector was generated for each gene by cloning 300-500-bp homology arms from the gene into a reporter plasmid, flanking the frt-Neo-frt-reporter cassette. For recombineering, BAC targeting cassettes were excised by restriction digestion, and electroporated into competent SW105 cells containing the BAC clone of interest. Targeted BAC clones were selected for KanR, and correctly targeted BAC clones were identified by a panel of PCR primers and restriction digestions. frt-Neo-frt selection cassette was removed by arabinose-mediated transient FLP recombinase expression in SW105 (43,44). BAC DNA was purified with a NucleoBond Xtra Midi kit (Macherey-Nagel) and injected into the pronuclei of fertilized one-cell eggs from ICR mice. Typically 300-400 fertilized eggs were injected. Potential founder animals were screened by PCR of tail DNA. Founder lines having a single copy of BAC transgene were selected by real-time PCR and used for subsequent analysis.

Knock-in mice

Generation of N-terminal reporter-fusion knock-in constructs was conducted using BAC recombineering. We used the pMCS-DTA retrieval vector (Gift from Dr. Kosuke Yusa, Osaka University, Japan) as the backbone of our knock-in vectors. pMCS-DTA contains the diphtheria toxin fragment-A (DTA) gene driven by the MC1 promoter for negative selection in ES cells. Knock-in cassette fragments were retrieved from modified BAC clones into pMCS-DTA by recombineering. BAC targeting was performed similarly to that of transgene construction of BAC Tg mice as described above. The first exon and the initial part of the first intron sequences were inserted between reporter (Venus or ELuc) coding sequence and the frt-PGK-EM7-Neo-frt cassette, so that frt-PGK-EM7-Neo-frt was inserted into the first intron region. A BAC targeting vector was generated for each gene by cloning 300-500-bp homology arms from the gene into a reporter plasmid. Targeted BAC clones were selected for KanR, and confirmed by a panel of PCR primers and restriction digestions. A correctly targeted BAC clone was used for generating the knock-in construct by the BAC retrieval method (43). The 5'- and 3'-homology arms in the retrieval vector were designed such that between 3- and 8-kb DNA segments flanking the reporter-frt-PGK-EM7-Neo-frt cassette in the BAC clone

were subcloned into pMCS-DTA. The total length of homology (3- and 8-kb on either side) was sufficient for gene targeting in ES cells (TT2). The shorter homology arm was used to design PCR-based screening for targeted ES cells. Southern blot hybridization was performed to confirm successful homologous recombination. Chimeric mice were produced from successfully targeted ES cell clones by aggregation with ICR embryos. Germ line transmission of the targeted allele was assessed by PCR of tail DNA.

Monolayer neural progenitor cell (NPC) culture

NPC culture was prepared and maintained using NS cell culture method, as described previously (30). Basal forebrain regions, including the medial, lateral and caudal ganglionic eminences, were excised from perinatal mice, and digested with Papain (Worthington) for 20 min at 37°C and dissociated completely by pipetting. Papain inhibitor was added, and then the cells were spun down, and resuspended in serum-free culture medium (NS-A media (Euroclone) plus N2 supplement (R&D Systems), 10 ng/ml of both basic FGF and EGF (Invitrogen), and penicillin/streptomycin). Culture dishes were coated with poly-L-ornithine (Sigma) and fibronectin (R&D Systems). In this study, acutely dissociated NPCs or established NS cells (at least 10 passages and 1 cryopreservation) were used. Detailed protocols for routine handling of NS cells were previously described (30).

Neuronal, astrocyte and oligodendrocyte differentiation of NPCs

Differentiation of NS cells was induced as described previously (30). For neuronal differentiation, NS cells were harvested using Papain to detach cells and $0.5-1.0 \times 10^4$ cells were re-plated into a poly-L-ornithine/fibronectin coated 35 mm dish in NS-A medium supplemented with 0.5μM retinoic acid (Sigma), N2, and B27 supplement. Rapid differentiation of NS cells to GFAP-positive astrocytes occurred within 2 days of exposure of NS cells to 80 ng/ml LIF (Millipore) and 80ng/ml BMP4 (R&D Systems). For oligodendrocyte differentiation, NS cells were harvested using Papain to detach cells and $0.5-1.0 \times 10^4$ cells were re-plated into a poly-L-ornithine/fibronectin coated 35-mm dish in NS-A medium supplemented with N2, 10ng/ml PDGF (R&D Systems) and 30ng/ml 3,3,5-triiodothyronine (T3; Sigma).

NPC transfection

NS cells were nucleofected using an AAD-1001 nucleofector device with mouse NS cell nucleofector solution (Amaza), program A-033, and 5 μg of DNA per 1.0×10^6 cells. Cells were analyzed 48 hr after nucleofection.

Lentiviral vector production and transduction of NPCs

Coding sequences of gene of interest were inserted into multiple cloning sites of CSII-EF-MCS (45). Lentiviral particles were produced via calcium phosphate cotransfection of 293T cells with the packaging plasmids in the same procedure as previously described (45). Supernatants were collected starting from 24 hr after the transfection for 36 hr and concentrated by centrifugation at 6,000 g for 16 hr. The

resulting viral pellet was resuspended in PBS at 1/500th of the original volume, and the viral aliquot was then frozen. Viral titers were approximately 10^9 infectious units/ml. Cultured NS cells were infected by purified lentiviral particles with MOI = approximately 10-20, and analyzed 48 hr after infection.

Immunocytochemistry

Cells were washed by phosphate-buffered saline (PBS) and fixed with 4% paraformaldehyde (PFA)/PBS for 20 min at room temperature. Fixed cells were washed by PBS, then blocked and permeated with 5% normal donkey serum (NDS) and 0.1% Triton X-100/PBS at room temperature for 20 min, incubated with primary antibodies diluted in PBS containing 1% NDS overnight at 4°C, washed with PBS, and then incubated with regular secondary antibodies conjugated to Alexa 488, Alexa 594 or Alexa 647 (1:200, Invitrogen) for 1 hr at room temperature. Stained cells were photographed with LSM510 or LSM780 confocal microscopes (Zeiss).

Immunohistochemistry

Embryos were fixed in 4% PFA/PBS for 3 hr or overnight at 4°C, washed in ice-cold PBS, equilibrated in 20% sucrose/PBS at 4°C, embedded in OCT compound (Sakura Finetek), and frozen at -80°C. Pups and adult mice were deeply anesthetized and perfused transcardially with 30 ml of PBS and 30 ml of 4% PFA/PBS. Brains were postfixed in the perfusing solution overnight at 4°C and then cryoprotected for 48 hr in 20% sucrose in PBS. Brains were embedded in OCT compound, and frozen at -80°C. Sections were made at 16- μ m thickness using a cryostat, and incubated in 5% NDS and 0.1% Triton X-100/PBS at room temperature for 1 hr, and with primary antibodies diluted in 0.1% Triton X-100/PBS containing 1% NDS overnight at 4°C. Sections were washed with PBS, and incubated with secondary antibodies conjugated to Alexa 488, Alexa 594 or Alexa 647 (1:200, Invitrogen) for 2 hr at room temperature. Then, sections were mounted with Fluormount-G (Southern Biotech) and photographed with LSM510 or LSM780 confocal microscope (Zeiss). Immunostaining for NICD was done, as previously described (46).

Antibodies

The following primary antibodies (final dilution for immunohistochemistry and source) were used: rabbit anti-GFP (1:500; Invitrogen A11122), rat anti-GFP (1:200; Nacalai tesque GF090R), rabbit anti-DsRed (1:500; Clontech 632496), rat anti-HA (1:200; Roche 3F10 clone), rabbit anti- β III-Tubulin (1:500; Covance A11122), mouse anti- β III-Tubulin (1:500; Covance MMS-435P), rabbit anti-GFAP (1:500; DAKO Z033429), mouse anti-GFAP (1:500; Sigma G3893), rabbit anti-CNPase (1:500; CST 5664S), mouse anti-Nestin (1:500; BD Pharmingen 556309), rabbit anti-PH3 (1:500; Millipore 06-570), rabbit anti-Hes1 (1:500), guinea pig anti-Hes1 (1:500), mouse anti-Ascl1 (1:500; BD Pharmingen 556604), rabbit anti-Olig2 (1:500; IBL 18953), mouse anti-Olig2 (1:500; Millipore MABN50), rabbit anti-Sox2 (1:500; Millipore AB5603), and rabbit anti-NICD (1:500; CST 4147S).

RNA *in situ* hybridization

RNA *in situ* hybridization was performed using digoxigenin-labeled Luc2 and Eluc antisense RNA probes, as described previously (47).

Fluorescence-activated cell sorting (FACS)

NPCs were dissociated with Papain (Worthington), washed with DMEM/F12 supplemented with N2 supplement (R&D Systems) and 0.1% BSA, and collected by centrifugation. Large clumps of cells were removed using a cell strainer (BD Biosciences). Cells were sorted and analyzed on a flow cytometer (ARIA II; BD Biosciences). The fluorescence activities of Venus and mCherry were detected in the FITC (Ex = 488nm) and Grn PE (Ex = 561nm) channel, respectively. NPCs were sorted to DMEM/F12 supplemented with N2 supplement (R&D Systems) and 0.1% BSA, and collected by centrifugation. For differentiation assays, NPCs were directly sorted to serum-containing differentiation medium; DMEM/F12 supplemented with N2 supplement (R&D Systems), B27 supplement (Invitrogen), 10% fetal bovine serum and penicillin/streptomycin.

Neurosphere assay

Neurosphere assays were performed from FACS-purified NPCs as described previously (48). Cells sorted by FACS were collected by centrifugation and re-suspended in neurosphere medium (N2 supplement (R&D Systems), B27 supplement (Invitrogen), 20ng/ml of EGF (Invitrogen) and 20ng/ml of bFGF (Invitrogen), and penicillin/streptomycin). Cells were counted and plated in uncoated 35-mm dishes (50,000 cells per dish). Primary neurospheres were counted 7 days after plating, and neurospheres were passaged by harvesting them by centrifugation (200g for 5 min) and triturating them in 100μl of medium with an automatic pipetter (P200 Gilson).

Differentiation assay

Cells sorted by FACS were collected by centrifugation and re-suspended in serum-containing differentiation medium, and then seeded in poly-L-ornithine- and fibronectin-coated 35-mm dishes (50,000 cells per dish). After 7 days in culture, cells were fixed and analyzed by immunocytochemistry. Data are presented as mean $\pm$ SEM from at least n=6 independent experiments counting >200 cells from randomly selected fields per each experiment.

Luminescence imaging of NPCs

NPCs carrying reporters were plated to coated 35-mm glass-base dishes at 50-60% confluence and incubated at 37°C and 5%CO₂. Cells were imaged just after plating or next day. 1mM luciferin was added to the culture medium. Bioluminescence images were acquired by an upright microscope (IX81; Olympus) with x60 dipping objective (1.42 NA). Digital images were acquired using a cooled CCD camera (iKon-M DU934P-BV, Andor). The filters and camera control were adjusted automatically using software (Meta

Morph; Universal Imaging Corp.). Stray light was cut off by turning off the electric system. The imaging system was used in a dark room. For dual-color bioluminescence imaging, we used only bandpass emission filters (FF01-510/84-25 for Eluc and BLP01-635R-25 for Red luc, Semrock). Luciferase-reporter mice were crossed with DCX-DsRed (41) Tg mice for monitoring neuronal differentiation or with pCNP-Venus mice for monitoring oligodendrocyte differentiation, and NPCs were collected from the double Tg mice. To monitor the cell cycle phases, luciferase-reporter mice were crossed with pCAG-mAG-hGem(1/110) (42) & pCAG-mKO2-hCdt1(30/120) (42) mice, and NPCs were collected from the triple Tg mice.

Organotypic slice culture for luminescence imaging

Time-lapse imaging of brain slices was performed, as described previously (49). Embryos were harvested in PBS, and brains were isolated in DMEM/F-12 supplied with 10mM HEPES. Brain tissue was immediately transferred into a silicon rubber-coated dish with DMEM/F-12 containing 10mM HEPES, which was previously bubbled with 100% O₂ for 10–15 min on ice. Meninges were removed, and coronal brain slices (100–200-μm thickness) were manually prepared by ophthalmic microsurgical knife (Alcon). Slices of basal telencephalon were transferred to a glass-base dish containing slice culture medium (DMEM/F-12 supplemented with N2, B27, 20ng/ml EGF, 20ng/ml bFGF, 5% horse serum, and 5% fetal bovine serum). Slices were immersed in about 200μl of type Ia collagen (Cellmatrix, Nitta Gelatin) (diluted to 1.5mg/ml with DMEM/F-12 and neutralizing buffer according to the manufacturer's instructions and kept on ice until use) at room temperature. After 20-min incubation at 37°C, slices were cultured at 37°C in 1ml of slice culture medium containing 1mM luciferin. Then, the dish was placed on a stage of inverted microscope and maintained at 37°C in 5% CO₂ and 45% O₂. Bioluminescence from the sample was acquired using the CCD camera, as described above.

Fluorescence imaging of NPCs

Fluorescent live cell images were acquired using a confocal laser scanning microscope, LSM 780 (Carl Zeiss), equipped with the spectral GaAsP array detector. NPCs were plated to coated 35-mm glass-base dishes at 50-60% confluence and incubated at 37°C and 5% CO₂. Venus and mCherry fluorescent protein were activated by 514-nm Argon laser and 561-nm DPSS laser, respectively. Images were acquired with the photon-counting mode. Spectral imaging was performed using a 32-channel GaAsP detector of the LSM 780 system, and specific Venus or mCherry fluorescent signal was separated from autofluorescence by applying linear unmixing algorithms (Carl Zeiss).

Image analysis and quantification

Image analysis was performed using ImageJ software and custom plug-ins. Custom written code of ImageJ plug-ins used in this study is available on request.

For analyzing an image sequence file of bioluminescence imaging, 'Spike-noise filter' was applied to a stack file to remove noise signals caused by cosmic rays. CCD

readout noise was also removed by ‘Temporal background reduction filter’. In this normalization procedure, the background value measured in the outside of the imaging regions for each time-frame was subtracted from the signal intensity. Tracking individual cells and quantification of bioluminescence signals were conducted with ‘Circadian Gene Expression (CGE)’ (<http://bigwww.epfl.ch/sage/soft/circadian/>). In some experiments, nuclear localized mCherry was expressed by nucleofection or lentivirus vectors, and used to detect and track moving cells. Average signal intensity inside the nucleus were measured, illustrated and analyzed by Prism 5.0 software (GraphPad Software).

Fixed monolayer NPCs were immunostained, and images were acquired with a Zeiss Axio Observer.Z1 inverted microscope with a 20x Plan-Apochromat objective (0.8 NA) or 40x Plan-Apochromat objective (1.3 NA). Automated segmentation was performed, and data was analyzed using custom written code (Static particle analyzer) in ImageJ. Histogram and scatter plot of protein levels in single cells were illustrated and analyzed by Prism 5.0 software.

Ascl1 expression by light-switchable gene expression system

Codon-optimized GAVPO (36) (blue light-activatable Gal4 transcriptional activator, hGAVPO) was subcloned into pEF-BOS expression vector for *ex utero* electroporation and CSII-EF-MCS-IRES2-Bsd plasmid (45) for lentivirus production. Bsd is the resistance for blasticidin. CSII-EF-MCS was digested with AgeI to remove EF promoter, and 5x UAS sequence and 3'-untranslated region (UTR) of mouse *Ascl1* gene was cloned in the opposite orientation to the LTR-mediated transcription. NLS-Ub-luc2 or Ascl1 coding sequences were inserted immediately after the 5x UAS sequence.

Using the CSII-EF-hGAVPO-IRES2-Bsd, CSII-UAS-NLS-Ub-luc2 or CSII-UAS-Ascl1 plasmids, lentiviral particles were produced and purified as described above. Established wild-type or Ascl1-mutant NS cells were co-infected with EF-hGAVPO-IRES2-Bsd&UAS-NLS-Ub-luc2 or EF-hGAVPO-IRES2-Bsd&UAS-Ascl1 lentiviral particles, and blasticidin S (20µg/ml; Invitrogen)-resistant cells were selected. Blasticidin-selected cells were passaged 3- to 5-times before analysis.

For generating oscillatory expression of transgene, blue-light was illuminated for 1 min with a 3-hr interval. For achieving sustained expression of transgene, blue-light was illuminated for 2 min with a 30-min interval, unless otherwise noted. Blue light was generated by pE-2 LED excitation system (CoolLED) equipped with 470-nm LAM and illuminated to cells through the x40 objective lens (UPLFLN40XO). Light-intensity was adjusted to 1 to 7%. Measured light power (LED = 1%) was approximately 200µmol/m²/s in this experimental condition. Blue-light illumination was automatically controlled using Meta Morph software. In the analysis of cell-proliferation or differentiation analysis, blue-light was generated by LEDB-SBOXH (OptoCode) in CO₂-incubators. Light power was changed from 0.16µmol/m²/s to 1.11µmol/m²/s. To analyze the effects of oscillatory or sustained expression on cell proliferation and neuronal differentiation, plated NPCs were illuminated for 72 hr and analyzed by immunocytochemistry. Data are presented as mean ± SEM from at least n=3 independent experiments counting >200 cells from randomly selected fields per each experiment.

Ascl1-light inducible system was introduced into dorsal telencephalon progenitors. pEF-mCherry-NLS, pEF-hGAVPO and CSII-UAS-NLS-Ub-luc2/CSII-UAS-Ascl1 plasmids were mixed at 2:3:5 ratio, and co-transfected into E14.5 dorsal telencephalon progenitors by *ex utero* electroporation. Plasmid DNA (2.5µg/µl) was microinjected into a telencephalic ventricle, and *ex utero* electroporation (5 pulses, 50mV, square wave generator (CUIY21, BEX), 5-mm paddle electrodes) was performed for transfection of plasmids into progenitors at the ventricular surface of the neocortex. Brains were immediately dissected, embedded in 3% low-melting point agarose, cut into 250-µm organotypic slices with a vibratome (VT1000; Leica), transferred to 35-mm well culture insert (353090, BD Falcon), and cultured in slice culture medium. Slices were incubated at 37°C, 5%CO₂ under the periodic blue-light illumination. For analyzing cell fate specification of transfected NPCs, electroporated hemispheres were immediately dissociated by Papain and plated to coated 35-mm glass-base dishes at 50-60% confluence, and incubated at 37°C and 5% CO₂.

Statistical Analysis

Statistical analyses were performed with Prism 5.0 software (GraphPad). *P* values less than 0.05 were considered to be significant. Statistical methods used in the analysis were described in figure legends.

Supplementary Text:

Hes1 represses the expression of itself and Dll1 (a ligand for Notch signaling) of the same cell, while Hes1 expression is up-regulated by Dll1 of the neighboring cells (Fig. 1). We show through a simple mathematical model that this regulatory pathway generates oscillation and suppression of Hes1 expression in the interacting cells. The model for the dynamics of Hes1 and Dll1 is given by the following equations,

$$\dot{H}_i(t) = V_H \frac{D_{\langle i \rangle}(t)^2}{D_{\langle i \rangle}(t)^2 + K_{HD}^2} \frac{K_H^2}{H_i(t - \tau_H)^2 + K_H^2} - d_H H_i(t), \quad (1)$$

$$\dot{D}_i(t) = V_D \frac{K_{DH}^2}{H_i(t)^2 + K_{DH}^2} - d_D D_i(t), \quad (2)$$

$$D_{\langle i \rangle}(t) = \begin{cases} D_j(t) & \text{(two-cell model, } j \neq i) \\ \sum_{j \neq i, |\vec{r}_j(t) - \vec{r}_i(t)| < I} D_j(t) & \text{(multicell model).} \end{cases} \quad (3)$$

Here, i, j are the labels for cells, which are 1 or 2 in the two-cell model, and $1 \leq i, j \leq N$ in the multicell model. $H_i(t)$ and $D_i(t)$ are the protein level of Hes1 and Dll1 in cell i , respectively. V_H and V_D are the maximum synthesis rates, and d_H and d_D are the degradation rates of the corresponding proteins. τ_H in Eq. (1) is the time required for Hes1 to affect its own formation in the same cell through the negative feedback loop (50). $D_{\langle i \rangle}(t)$ is the total Dll1 input that cell i receives at time t from neighboring cells. In the multicell model, the two-dimensional position of cell i at time t is denoted as $\vec{r}_i(t) = (x_i(t), y_i(t))$, and the sum in Eq. (3) is taken over the cells that are in the positions close enough to cell i (length = $|\vec{r}_j - \vec{r}_i| < I$). K_{HD} , K_H and K_{DH} correspond to the typical amount of Hes1 or Dll1 that account for the enhancement or repression. Although it is more realistic to introduce time delays to $D_{\langle i \rangle}(t)$ in Eq. (1) and $H_i(t)$ in Eq. (2), we have confirmed that the basic features of the model remain the same in the absence of such time delays when $d_D \lesssim d_H$. We set all

Fig. 1: Schematic structure for the Hes1 and Dll1 regulatory pathway. H_i and D_i correspond to the protein level of Hes1 and Dll1 in cell i , respectively. Cells interact through the Notch signaling activation induced by Dll1.

the Hill coefficients to be 2, following the notion that Hes1 and Dll1 act as dimers. Assuming larger Hill coefficients does not change the qualitative dynamics.

Fig. 2: Numerical simulation of the two-cell model given by Eqs. (1,2). Lines show the time series of protein levels (arbitrary units) after transient time. The Hes1 protein level of one of the cells shows a clear oscillatory behavior with period ~ 2.7 h, whereas in the other cell it becomes almost quiescent. This behavior is reproduced for any given random initial condition. We used the parameter values $\tau_H = 1$ [h], $d_H = 2.1$ [h $^{-1}$] (both estimated from experiments), $d_D = 1.5$ [h $^{-1}$], $V_H = 50$, $V = 5$, $K_{HD} = 1$, $K_H = 1.5$, and $K_{DH} = 0.1$.

First, we show the result for the two-cell case (Fig. 2). Although the equations (1) and (2) are symmetric in $i = 1, 2$, the average level of Hes1 takes two discrete values in the two cells. This is due to the mutual (lateral) inhibition effect of Dll1 through Hes1, and whether cell 1 or 2 keeps the higher Hes1 level is determined by the randomly given initial condition. In Fig. 2, the high Dll1 level in cell 2 activates Notch signaling in cell 1, yielding the high, oscillatory Hes1 expression in cell 1. Such self-sustained oscillation occurs in a delayed feedback model in the condition that $H_i(t)$ is sufficiently expressed (51). Dll1 expression in cell 1 is suppressed by the high Hes1 expression, and consequently the Notch signaling level in cell 2 is insufficient to produce abundant Hes1.

Next, we construct the multicell model. Considering that neural progenitor cells move slowly *in vivo*, we artificially model the motion of each cell by an overdamped Brownian motion in the two-dimensional space. We further assume an attracting force between cells, modeled by a linear elastic force with the natural length L and stiffness k , to incorporate the fact that cells do not disperse *in vivo*. The equation of motion is given by,

$$\dot{\vec{r}}_i(t) = -\frac{\partial}{\partial \vec{r}_i} U(\vec{r}_1, \vec{r}_2, \dots, \vec{r}_N) + \vec{\xi}_i(t), \quad (4)$$

$$U(\vec{r}_1, \vec{r}_2, \dots, \vec{r}_N) = \sum_{i,j > i, |\vec{r}_j(t) - \vec{r}_i(t)| < C} \frac{1}{2} k (|\vec{r}_j(t) - \vec{r}_i(t)| - L)^2, \quad (5)$$

where $U(\vec{r}_1, \vec{r}_2, \dots, \vec{r}_N)$ is the “potential” that mimics the motional interaction between the cells. The potential confines the neighbor cells at a typical distance L , which should serve as a model for cell adhesion. The cutoff length C is introduced since cell adhesion occurs only between neighboring cells. $\vec{\xi}_i(t) = (\xi_i^x(t), \xi_i^y(t))$ is the noise, satisfying $\langle \xi_i^x(t) \xi_j^x(s) \rangle = \langle \xi_i^y(t) \xi_j^y(s) \rangle = A \delta_{ij} \delta(t - s)$ and $\langle \xi_i^x(t) \xi_j^y(s) \rangle = 0$, with $\langle \rangle$ being the ensemble average. Simulation of this multicell model including cell division (method shown in the caption of Fig. 3) expresses the feature that the random motion

Fig. 3: Numerical simulation of the multicell model [Eqs. (1,2) and Eq. (4)]. We used the same parameter values as those in Fig. 2 for Eqs. (1,2), except for K_{HD} . We set $K_{HD} = 1$, since the cells typically interact with 6 neighbor cells in our multicell model. For the motion of the cells [Eq. (4)], we used the parameters $L = 1$ (unit of cell size), $I = C = 1.25$, $A = 0.04$, and $k = 8$. We initially prepared $N = 60$ cells, and assumed that the cells undergo cell division every 24h (thus N increases with time). In the event of the division, the Hes1 and Dll1 values were equally shared between the two daughter cells. The initial positions of the cells were given randomly in a relatively small region. **a)** Snapshot of the cell position and Hes1 level (color scale) in the simulation. The typical interval between the center of cells (depicted by the circle with diameter 0.5) is approximately $L(= 1)$ due to the motional interaction [Eq. (5)]. The green color scale corresponds to the relative level of $H_i(t)$ (Hes1); green cells are mostly oscillating, whereas the black cells are in the quiescent phase (low Hes1 and high Dll1 level). **b)** The typical time courses of Hes1 level in 4 cells in the multicell simulation. Some cells are in the oscillatory phase (cell 1), whereas others stay in the quiescent phase (cell 4). Because the random motion and cell division provide relatively strong perturbation to the cells, some cells experience both the Hes1 oscillatory and quiescent phases during the time course (cells 2 and 3). Cells that are stuck in the quiescent phase may express *Ascl1* in a sustained manner, and later differentiate into neurons.

as well as the proliferation of the cells allow single cells to switch back and forth between the Hes1 positive and negative phases (cells 2 and 3 in Fig. 3b), corresponding to the two phases observed in the previous two-cell model (Fig. 2).

Fig. S1. Reporter-fusion BAC Tg constructs for monitoring protein expression dynamics of transcription factors.

(F) Venus-Olig2 fusion BAC Tg mouse. (G) Luc2-Sox2 fusion BAC Tg mouse. Coding region is shown in grey. More detailed information is described in text and Supplementary Table S1.

Fig. S2. Reporter-fusion knock-in strategy for monitoring expression dynamics of Hes1 and Hes5 proteins.

(A) Venus-Hes1 fusion knock-in mouse. (B) Venus-Hes5 fusion knock-in mouse. (C) ELuc-Hes5 fusion knock-in mouse. Closed box indicates coding region. More detailed information is described in text and Supplementary Table S1.

Fig. S3. Faithful reporter expression in the reporter mice.

(A-D) *In situ* hybridization for *Luc2* (A-C) and *Eluc* (D) mRNA of luciferase-reporter mice at E12.5. Coronal sections of the brains of *Luc2*-Hes1 fusion BAC Tg mouse (A), pHes5-NLS-Ub-Luc2-Tg mouse (B), *Luc2*-Ascl1 fusion BAC Tg mouse (C) and *ELuc*-Hes5 fusion knock-in mouse (D). (E-J) Immunofluorescence for Venus (E-I) or mCherry (J) of coronal sections of Venus-Hes1 fusion knock-in mouse (E,F), Venus-Hes5 fusion knock-in mouse (G), Venus-Ascl1 fusion BAC Tg mouse (H), Venus-Olig2 fusion BAC Tg mouse (I), and mCherry-Olig2 fusion BAC Tg mouse (J). Double immunolabelling for Nestin (red in F) and Olig2 (green in J) was performed. GE, Ganglionic eminence.

Fig. S4. Correlation between reporter and endogenous protein expression. NPC cultures were prepared from reporter-fusion Tg or knock-in mice. (A-G) Representative images of immunocytochemistry indicating well-correlated reporter protein expression to endogenous protein expression. (H) Scatter plot of Hes1 protein levels versus HA-Luc2-Hes1 fusion protein levels. Each point represents Hes1 protein and HA-Luc2-Hes1 fusion protein signals in a single cell. (I) Ascl1 versus HA-Luc2-Ascl1. (J) Olig2 versus HA-Luc2-Olig2. (K) Sox2 versus HA-Luc2-Sox2. (L) Hes1 versus Venus-Hes1. (M) Ascl1 versus Venus-Ascl1. (N) Olig2 versus mCherry-Olig2. Luciferase and fluorescent reporter expression correlated very well with endogenous protein expression in NPCs.

Fig. S5. Normal brain development of the reporter mice and their normal differentiation competency of NS cells.

(A-E') HE staining of the coronal sections of the adult brain from wild-type (A,A'), homozygous Venus-Hes1 fusion knock-in (B,B'), heterozygous Luc2-Hes1 fusion BAC Tg (C,C'), heterozygous Luc2-Ascl1 fusion BAC Tg (D,D'), heterozygous Luc2-Olig2 fusion BAC Tg (E,E') mice. The dorsolateral region of the subventricular zone of the lateral ventricle is enlarged in (A'-E'). (F-H) NS cells were generated from wild-type, homozygous Venus-Hes1 fusion knock-in, heterozygous Luc2-Hes1 fusion BAC Tg, heterozygous Luc2-Ascl1 fusion BAC Tg, and heterozygous Luc2-Olig2 fusion BAC Tg mice. These NS cells were transferred to a differentiation medium containing serum, and analyzed 7 days later by immunocytochemistry. Their competency to generate neurons, astrocytes, and oligodendrocytes was not distinguishable between all genotypes. ns: not significant, one-way ANOVA followed by Bonferroni *post hoc* test.

Fig. S6. Variable expression levels of bHLH factors in self-renewing NPCs.
(A-D) Proliferating NPCs were immunostained with anti-Sox2 (A), anti-Hes1 (B), anti-Ascl1 (C), and anti-Olig2 (D) antibodies. Hes1, Ascl1, and Olig2 expression levels were variable while another NPC-specific factor, Sox2, was expressed at a relatively constant level. (E-I) Histograms of mean normalized Sox2, Hes1, Venus-Hes5, Ascl1, and Olig2 staining intensity in proliferating NPCs. (J) Comparison of the standard deviations of the expression levels. The variability of Sox2 expression was very small compared to the other factors. * $p < 0.05$, *** $p < 0.001$; two-tailed Student's t -test.

NS cells

Differentiated cells from NS cells

I Neuron

J Astrocyte

K Oligodendrocyte

Fig. S7. Abnormal differentiation competency of NS cells mutant for bHLH factors.

NS cells were generated from wild type (A-A'''), Hes1-KO (B-B'''), Ascl1-KO (C-C'''), and Olig2-KO (D-D''') mice. These NS cells were immunostained with anti-Nestin (NPC marker), anti- β III-tubulin (neuron marker), anti-GFAP (astrocyte marker), and anti-CNPase (oligodendrocyte marker) antibodies. 15% of Hes1-KO cells expressed β III-tubulin, and 5.5% of Ascl1-KO cells and 53% of Olig2-KO cells displayed GFAP expression before induction of differentiation. (E-K) These NS cells were transferred to a differentiation medium containing serum, and analyzed 7 days later by immunocytochemistry. Their competency to generate neurons, astrocytes, and oligodendrocytes was significantly reduced in the absence of Ascl1, Hes1, and Olig2, respectively. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$, one-way ANOVA followed by Bonferroni *post hoc* test.

(F) Quantification of the *Nestin* promoter activity in NPCs. (H) Quantification of the *Rosa26* promoter activity in NPCs. Reporter constructs were transfected to NPCs by nucleofection.

Fig. S15. Correlation between bHLH protein expression in self-renewing NPCs. (A-C) Representative images of immunocytochemistry of NPCs. (D) Scatter plot of Ascl1 protein levels versus Venus-Hes1 fusion protein levels. Each point represents Ascl1 protein and Venus-Hes1 fusion protein signals in a single cell. (E) Olig2 versus Venus-Hes1. (F) Ascl1 versus Olig2.

Fig. S16. FACS analysis of variable expression levels of bHLH factors in self-renewing NPCs.

NPC cultures were prepared from fluorescent reporter-fusion knock-in mice or BAC Tg mice; Venus-Hes1 (**A,D,G,J,M,P**), Venus-Ascl1 (**B,E,H,K,N,Q**), or mCherry-Olig2 (**C,F,I,L,O,R**). (**A-C**) Expression levels and dynamics of bHLH factors were analyzed by FACS. Hes1, Ascl1, and Olig2 expression levels were variable. (**D-L**) Venus- or mCherry-low cells (the lowest 10% of the whole population) and Venus- or mCherry-high cells (the highest 10% of the whole population) were sorted and re-analyzed 2 days later. These populations returned to the original distribution of expression levels within 2 days when they were cultured in NS-cell culture medium. (**M-R**) Cells sorted by FACS were re-suspended in neurosphere medium, and plated in uncoated dishes. Primary neurospheres were counted 7 days after plating. Primary neurospheres were passaged and subjected to the secondary neurosphere assay. Hes1-high, Hes1-low, Ascl1-high, Ascl1-low, Olig2-high and Olig2-low fractions generated neurospheres at similar efficiencies. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$, one-way ANOVA followed by Bonferroni *post hoc* test.

Fig. S17. Different expression levels of bHLH factors bias the fate choice of NPCs. NPC cultures were prepared from fluorescent reporter-fusion knock-in mice or BAC Tg mice. **(A-C)** NPCs were separated by FACS into Hes1-high, Hes1-low, Ascl1-high, Ascl1-low, Olig2-high and Olig2-low fractions. After sorting, each cell population was immediately transferred to a differentiation medium, and analyzed 7 days later by immunocytochemistry. **(D-G)** NPC cultures derived from Venus-Ascl1 and mCherry-Olig2 double Tg mice were subjected to FACS analysis. 5% of the total population depending on Ascl1 and Olig2 expression levels (Ascl1-high & Olig2-low, Ascl1-high & Olig2-high, Ascl1-low & Olig2-low, or Ascl1-low & Olig2-high) was sorted, and their differentiation competency was analyzed. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$, one-way ANOVA followed by Bonferroni *post hoc* test.

Fig. S18. Hes1 and Ascl1 expression dynamics during NPC division.

(A) Temporal trajectories of Luc2-Hes1 just before NPC or neurogenic division at time = 0 (mean in solid line and standard errors in colored, $n > 30$ for each division) were obtained by time-lapse analysis of NS cells derived from Luc2-Hes1 fusion BAC Tg mice (division-mode effect, $p = 0.0016$; interaction between division-mode and time, $p < 0.0001$, repeated measures ANOVA). (B) The frequency of transient up-regulation (at least two-fold compared to the average) of Ascl1 expression before cell division. (C-F) Acute dissociation cultures were prepared from the ventral telencephalon of Luc2-Hes1 fusion BAC Tg mice. Quantification of Luc2-Hes1 fusion protein dynamics during P-P (C,D) and N-N divisions (E,F). P-P, symmetric division that generates two NPCs; N-N, symmetric division that generates two neurons.

Fig. S19. Variable Notch signaling activities in NPCs.

(A-G) NICD immunofluorescence was analyzed in embryonic brain sections (A-C) and cultured NPCs (D-G). NICD levels were lower near the apical side, where cells at the late G2 and early G1 phases were present. The boundary between VZ and SVZ was highlighted by white broken line. NICD expression levels were variable as that of bHLH factors in self-renewing NPCs (D-G). (H) Reporter construct for monitoring active NICD-RBPjk complex. (I) This reporter construct is not susceptible to Hes1/5 negative autoregulation because it does not contain Hes-binding sites, unlike the *Hes* promoters. Thus, the cellular activity of NICD-RBPjk complex can be faithfully monitored by this reporter. (J,K) The activity of NICD-RBPjk complex was dynamic in some NPCs (J), but was less dynamic in others (K). **** $p < 0.0001$, one-way ANOVA followed by Bonferroni *post hoc* test.

Fig. S20. Stable oscillation of *Hes5* expression in NPCs whose Notch signaling is constantly active.

In NPCs, where NICD expression was constantly induced from the *Rosa26* locus (A), oscillatory expression of *Hes5* was dramatically stable (D,E,G, +Cre), compared with that in normal NPCs (B,C,F, -Cre). In normal NPCs, *Hes5* oscillation is frequently disrupted (B,C, blue and orange asterisks). Variation of *Hes5* oscillation periods in NPCs expressing NICD constantly was reduced compared with control (F-H).

Fig. S21. Stable oscillation of Hes1 expression in NPCs whose Notch signaling is constantly active.

In NPCs, where NICD expression was constantly induced from the *Rosa26* locus (A), oscillatory expression of Hes1 was dramatically stable (B,C,D, +Cre), compared with that in normal NPCs (Fig. 2A,G,H). Variation of Hes1 oscillation periods in NPCs expressing NICD constantly was reduced compared with control (D,E).

Fig. S22. Regulation of Ascl1 and Olig2 expression without Notch signaling.

NPCs derived from Luc2-Ascl1 (A,B) and Luc2-Olig2 (C,D) were treated with DAPT (γ -secretase inhibitor). Ascl1 and Olig2 expression was up-regulated in a sustained manner after DAPT treatment. Quantification of the reporter expression at cell population (A,C) and single cell levels (B,D) was displayed.

Fig. S23. Expression dynamics of bHLH factors during astrocyte differentiation.
(A) Astrocyte specification was induced at time = 0 by LIF and BMP4. GFAP expression was induced. (B,C) Quantification of Hes1 up-regulation during astrocyte differentiation. NPC, n=30; Astrocyte differentiation, n=21. Significance was analyzed by two-tailed Student's *t*-test. (D-G) Quantification of Luc2-Ascl1 (D,E) and Luc2-Olig2 (F,G) expression during astrocyte differentiation. Quantification of the reporter expression at cell population (B,D,F) and single cell levels (E,G) was displayed.

Fig. S24. Expression dynamics of bHLH factors during oligodendrocyte differentiation.

(A,B) Quantification of Luc2-Olig2 (A) and pCNP-Venus expression (B) in a single cell during oligodendrocyte differentiation, which was induced at time = 0 by T3. (C,D) Quantification of Luc2-Olig2 (C) and pCNP-Venus (D) expression in the same cells (Cell-2 and their daughter cells, Cell-2a and cell-2b) during oligodendrocyte differentiation, which was induced at time = 0 by T3. (E,F) Comparison of Olig2 expression levels at trough (E) and peak (F) of oscillation between NPCs and OPCs (oligodendrocyte precursor cells). Olig2 expression level in OPCs was significantly higher at trough than that in NPCs. Significance was analyzed by two-tailed Student's *t*-test. (G) Temporal trajectories ($n > 16$ cells) of Luc2-Olig2 (mean in solid line and standard errors in colored) and pCNP-Venus (mean in solid line and standard errors in colored). Time = 0 (asterisk) corresponds to time of rapid Olig2 down-regulation. (H-J) Ascl1 and Hes1 expression during oligodendrocyte differentiation. Scale bar, 12.5 μ m (H-J).

Fig. S25. Characterization of pCNP-Venus Tg mice.

(A) Schematic illustration of pCNP-Venus Tg construct. (B-F) Venus expression (green) was analyzed and compared with endogenous CNPase expression (red) in the adult brain (B-E) and differentiated oligodendrocytes *in vitro* (F).

Fig. S26. Experimental design for light-induced oscillatory/sustained expression of Ascl1 in NPCs.

(A) Strategy for the light-induced gene expression using humanized GAVPO (hGAVPO). (B) The schedule of light exposure. Ascl1 expression was induced in *Ascl1*-null NPCs. Repeated exposure of blue light with 3-hr intervals generated oscillatory expression with a 3-hr period, while repeated exposure with 30-min intervals generated sustained expression (Fig. 5A-K). (C) The schedule of light exposure. Sustained Ascl1 expression was induced in NPCs for indicated time lengths (Fig. 5L-P). Light intensity: ++, 1.11 $\mu\text{mol}/\text{m}^2/\text{s}$. (D-G) Ascl1 expression was induced in *Ascl1*-null NPCs according to the schedule of light exposure (fig. S26B) and examined at $t = 250$ min and 360 min in oscillatory and sustained expression, respectively (the light-induced condition was the

same as Fig. 5A-C). Representative images (**D**) and their quantitative data (**E**) of immunocytochemistry and western blot (**F**) and its quantitative data (**G**) are shown. Quantitative data (mean $\pm$ SEM) are expressed as fold-change over wild-type control. For western, Ascl1 protein levels were normalized using anti-tubulin. Here, the peak level of the light-induced Ascl1 oscillation and the level of the light-induced sustained Ascl1 expression were 3 to 6-fold and ~8-fold higher, respectively, than the endogenous average level in WT NPCs (**E,G**). Peaks of endogenous Ascl1 expression are several-fold higher than the average level of NPCs (Fig. 3, fig. S11), and therefore these light-induced levels are comparable to the endogenous peak levels in NPCs and differentiating neurons. $*p < 0.05$, $**p < 0.01$, $***p < 0.001$, $****p < 0.0001$; two-tailed Student's *t*-test.

Fig. S27. Oscillatory Ascl1 expression with 6-hour period did not affect the proportion of dividing cells in *Ascl1*-null NPCs.

(A) The schedule of light exposure. Oscillatory Ascl1 expression with 6-hr period was induced in *Ascl1*-null NPCs, which were cultured in the presence of bFGF and EGF.

(B,C) Oscillatory Ascl1 expression with 6-hr period induced virtually no β III tubulin⁺ neuron formation (B) and did not significantly increase the proportion of dividing cells (PH3⁺) (C). Significance was analyzed by two-tailed Student's *t*-test.

Fig. S28. Sustained *Ascl1* expression at lower levels induces neuronal differentiation in *Ascl1*-null NPCs.

(A) Repeated exposure with 30-min intervals by 1% LED power achieved sustained expression at comparable expression levels with the peak levels of oscillatory expression generated by blue light exposure with 3-hr intervals by 7% LED power. (B) The schedule of light exposure. *Ascl1* expression was induced in *Ascl1*-null NPCs, which were

cultured in the presence of bFGF and EGF, a condition that inhibits neurogenesis. Light intensity: +, $0.16\mu\text{mol}/\text{m}^2/\text{s}$; ++, $1.11\mu\text{mol}/\text{m}^2/\text{s}$. **(C-F)** Oscillatory Ascl1 expression induced virtually no $\beta\text{III tubulin}^+$ neuron formation **(C)** but significantly increased the proportion of dividing cells (PH3^+), compared to the control (Ub-luc2) **(D)**. Sustained Ascl1 expression at lower levels significantly increased $\beta\text{III tubulin}^+$ neuron formation **(E)** but did not affect the proportion of dividing cells (PH3^+), compared to the control (Ub-luc2) **(F)**. Data sets used in **(C,D)** were the same as that of Fig. 5D,E. *, $p < 0.05$; **, $p < 0.01$; two-tailed Student's *t*-test.

Fig. S29. Light-induced oscillatory/sustained expression of Ascl1 in wild-type NPCs. According to the schedule of light exposure (A), oscillatory (B-I) and sustained (J-Q) Ascl1 expression was induced in wild-type NPCs, which were cultured in the presence of bFGF and EGF, a condition that inhibits neurogenesis. Oscillatory light stimulation of a 3-hr period did not significantly affect the neurogenesis or proliferation of these cells (B-I). By contrast, sustained Ascl1 expression for 72 hr significantly increased neuronal formation with some tendency to reduce the proportion of dividing cells (J-Q). Light intensity: +, $0.16 \mu\text{mol}/\text{m}^2/\text{s}$; ++, $1.11 \mu\text{mol}/\text{m}^2/\text{s}$. The proportion of dividing cells was measured by immunostaining with anti-PH3 antibody. Cells having punctated signals in the nuclei were included in the PH3-immunopositive fraction in this study. * $p < 0.05$, ** $p < 0.01$; two-tailed Student's t -test.

Fig. S30. Sustained Ascl1 expression at lower levels induces neuronal differentiation in wild-type NPCs.

(A) 30-sec blue-light pulse with 30-min intervals achieved sustained expression at comparable expression levels with the peak levels of oscillatory expression generated by 1-min blue-light pulse with 3-hr intervals. (B) The schedule of light exposure. Ascl1 expression was induced in wild-type NPCs, which were cultured in the presence of bFGF and EGF. Light intensity: $1.11 \mu\text{mol}/\text{m}^2/\text{s}$. (C-F) Oscillatory light stimulation with 3-hr period did not significantly affect the neurogenesis or proliferation of these cells (C,D). By contrast, sustained Ascl1 expression at low levels for 72 hr significantly increased β III tubulin⁺ neuron formation (E) but did not affect the proportion of dividing cells (PH3⁺) (F). * $p < 0.05$; two-tailed Student's *t*-test.

stimulation with 3-hr period did not significantly affect the neurogenesis or maintenance of NPCs (**K,L**). By contrast, sustained *Ascl1* expression for 72 hr significantly induced premature neuronal formation (**M-P''**). Light intensity: +, 0.16 μ mol/m²/s; ++, 1.11 μ mol/m²/s. VZ, Ventricular zone; SVZ, Subventricular zone; IZ, Intermediate zone; CP, Cortical plate. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$; two-tailed Student's t -test.

19	Ascl1-KO	KO				(54)	
20	Olig2-KO	KO				(55)	

Table S1.

Genetically modified mouse strains used in this study. KO, knock-out; KI, knock-in.

Captions for Movies

Movie S1

Luc2-Hes1 expression in slice culture of the ventral telencephalon. Time in hr and min is indicated. Related to Fig. 1.

Movie S2

Luc2-Hes1 expression in self-renewing NPCs. Time in hr and min is indicated. Related to Fig. 2 and fig. S8.

Movie S3

Luc2-Ascl1 expression in self-renewing NPCs. Time in hr and min is indicated. Related to Fig. 2 and fig. S11.

Movie S4

Luc2-Olig2 expression in self-renewing NPCs. Time in hr and min is indicated. Related to Fig. 2 and fig. S12.

Movie S5

Luc2-Sox2 expression in self-renewing NPCs. Time in hr and min is indicated. Related to fig. S14.

Movie S6

Light-induced oscillatory/sustained gene expression in NPCs. Time in hr and min is indicated. Related to Fig. 5.
