Running title: Accuracy verification of IR Tracking with the Vero4DRT.
**Conflicts of interest:** This research was in part sponsored by Mitsubishi Heavy Industries, Ltd., Japan. Takashi Mizowaki, Masaki Kokubo, and Masahiro Hiraoka have consultancy agreements with Mitsubishi Heavy Industries, Ltd., Japan.

**Meeting presentation:** This research was presented orally, in part, at the American Association of Physicists in Medicine (AAPM) 54th Annual Meeting in Charlotte, July 29 to August 2, 2012.
Abstract

Purpose: To verify the accuracy of an infrared (IR) marker-based dynamic tumor-tracking irradiation system (IR Tracking) using the gimbaled x-ray head of the Vero4DRT (MHI-TM2000).

Methods and Materials: The gimbaled 6-MV C-band x-ray head of the Vero4DRT can swing along the pan-and-tilt direction to track a moving target. During beam delivery, the Vero4DRT predicts the future three-dimensional (3D) target position in real time using a correlation model (4D model) between the target and IR marker motion, and then continuously transfers the corresponding tracking orientation to the gimbaled x-ray head. The 4D-modeling error \(E_{4DM}\) and the positional tracking error \(E_P\) were defined as the difference between the predicted and measured positions of the target in 4D modeling and as the difference between the tracked and measured positions of the target during irradiation, respectively. For the clinical application of IR Tracking, we assessed the relationship between \(E_{4DM}\) and \(E_P\) for three 1D sinusoidal (peak-to-peak amplitude [\(A\): 20-40 mm, breathing period [\(T\]: 2-4 s]), five 1D phase-shifted sinusoidal (\(A\): 20 mm, \(T\): 4 s, phase shift [\(\tau\): 0.2-2 s]), and six 3D patient respiratory patterns.

Results: The difference between the 95\(^{th}\) percentile of the absolute \(E_P\) (\(E_{95}^{P}\)) and the mean (\(\mu\)) + two standard deviations (SD) of absolute \(E_{4DM}\) (\(E^{4SD}_{4DM}\)) was within ±1 mm for all motion patterns. As the absolute correlation between the target and IR marker motions decreased from 1.0 to 0.1 for the 1D phase-shifted sinusoidal patterns, the \(E^{4SD}_{4DM}\) and \(E_{95}^{P}\) increased linearly, from 0.4 to 3.0 mm (R = -0.98) and from 0.5 to 2.2 mm (R = -0.95), respectively. There was a strong positive correlation between \(E^{4SD}_{4DM}\) and \(E_{95}^{P}\) in each direction [(lateral, craniocaudal, anteroposterior) = (0.99, 0.98, 1.00)], even for the 3D respiratory patterns; thus, \(E_{95}^{P}\) was readily estimated from \(E^{4SD}_{4DM}\).

Conclusions: Positional tracking errors correlated strongly with 4D-modeling errors in IR.
Tracking. Thus, the accuracy of the 4D model must be verified before treatment, and margins are required to compensate for the 4D-modeling error.

Key words: Four-dimensional image-guided radiotherapy, dynamic tumor-tracking irradiation, intrafractional respiratory motion, gimbaled x-ray head, tracking accuracy.
I. INTRODUCTION

The International Commission on Radiation Units and Measurements (ICRU) recommends that the planning target volume (PTV) includes margins around a clinical target volume (CTV) to account for patient motion, tumor motion, and deformation due to respiration and uncertainties in beam placement. Particularly for thoracic and abdominal tumors, respiration is an important factor causing uncertainty during beam delivery. Several techniques, including respiratory gating, breath-holding, and dynamic tumor tracking (DTT), have been proposed to reduce the uncertainties caused by respiratory motion. Among these techniques, DTT can minimize the internal uncertainties without a prolonged treatment time or the burden of breath-holding for patients. There are two approaches to DTT: direct and indirect methods. While direct methods detect the target itself, indirect methods assess some surrogate quantity and deduce localization information based on the surrogate.

We have developed a novel four-dimensional (4D) image-guided radiotherapy system with a DTT function: the Vero4DRT (MHI-TM2000; Mitsubishi Heavy Industries, Ltd., Japan, and BrainLAB, Feldkirchen, Germany). Figure 1 shows a schematic diagram of the Vero4DRT. The Vero4DRT has several unique components that facilitate DTT irradiation: (1) a compact C-band 6-MV x-ray head with a gimbal mechanism, mounted on an O-ring gantry. The gimbaled x-ray head can rotate in both the pan (horizontal to the O-ring) and tilt (vertical to the O-ring) directions, (2) a gantry-mounted orthogonal kV x-ray imaging subsystem, consisting of two sets of x-ray tubes and flat-panel detectors, with a spatial resolution of 0.2 mm at the isocenter level, and (3) an extended version of the ExacTRAC system for the DTT function (BrainLAB) with an infrared (IR) camera mounted on the ceiling of the treatment room.

The Vero4DRT is capable of direct and indirect DTT approaches. One is an x-ray image-based direct DTT approach (X-ray Tracking). A moving tumor is tracked in real time
by either direct monitoring of the tumor itself or fiducial markers, using the kV x-ray imaging subsystem. However, the x-ray monitoring interval and image processing time delay cause prediction errors. Furthermore, continuous x-ray monitoring may result in two potential health hazards: deterministic and stochastic risks associated with the increased radiation dose delivered by the kV x-ray imaging subsystem. The other is an IR marker-based indirect DTT approach (IR Tracking), which is available clinically. An advantage of IR Tracking is a substantial reduction in imaging dose, compared with that of X-ray Tracking. During beam delivery, the Vero4DRT monitors the displacement of the IR markers on the abdominal wall continuously via the IR camera of the ExacTRAC system, and then tracks target motion using a correlation model (4D model) between the target and IR marker motions, as described in Section II. A.

A key issue in indirect DTT is the accuracy of the model predicting the internal target position based on the surrogate measurements. Several investigators have shown that the Synchrony Respiratory Tracking System, part of the Cyberknife indirect DTT system (Accuracy Inc., Sunnyvale, CA), was able to follow a moving tumor with high accuracy. Depuydt et al. verified the positional tracking accuracy of IR Tracking only under conditions of a perfect correlation between the target and IR marker motions using a prototype of the Vero4DRT, however, no dosimetric verification was performed. According to the report of the American Association of Physicists in Medicine Task Group 76, phase shifts between the internal tumor and external surrogate motion of > 1 s were observed in patients with lung cancer. The accuracy of a 4D model is unknown in the presence of such a phase shift. Additionally, tracking accuracy – based on the respiratory tumor and abdominal wall motions of real patients – should be verified before the clinical use of IR Tracking. Thus, in the present study, we verified the dosimetric and positional accuracy of IR Tracking.
II. MATERIALS AND METHODS

II. A. The 4D model for IR Tracking with the Vero4DRT

Figure 2 shows a schematic diagram of IR Tracking. Before irradiation, IR marker displacements on the abdominal wall and the implanted fiducial markers’ motion are monitored to create a 4D model for 20-40 s using the IR camera of the ExacTRAC system every 16.7 ms and the orthogonal kV x-ray imaging subsystem every 80 ms, using a stereovision technique. After monitoring, two target positions are determined: the detected target position and the predicted target position. The detected target position is indicated by the centroid of the polyhedron, composed from the implanted fiducial markers. The predicted target position is calculated from the 4D model, expressed by a quadratic equation involving two variables, the position and velocity of the IR markers. In the 4D-modeling phase, the peak-to-peak amplitude of the detected target motion ($A$) and the mean ($\mu$) and standard deviation (SD) of the absolute difference between the detected and predicted target positions are automatically calculated along each axis (Fig. 2). During beam delivery, the 3D target position is calculated from the displacements of the IR markers using the 4D model, and then the corresponding tracking orientation is transferred continuously to the gimbaled x-ray head.

The predicted target position can also be monitored visually in real time at a minimum interval of 1 s on intra-fractional fluoroscopic images.

II. B. Dosimetric and positional verification of IR Tracking

For the clinical application of IR Tracking, the following verifications were performed:

(1) Dosimetric and positional verification of 1D sinusoidal patterns with perfect correlation between the target and IR marker motions, using a motor-driven base.
(2) Positional verification of 1D sinusoidal patterns with miscorrelation between the
target and IR marker motions, using a dynamic anthropomorphic thorax phantom.

(3) Positional verification of 3D target and 1D surrogate motions, based on the patient’s
respiration, using a four-axis moving phantom.

II. B. 1. Dosimetric and positional verification of IR Tracking for 1D sinusoidal patterns

Figure 3(a) shows a photograph of the experimental system for the dosimetric and
positional verification of IR Tracking. The IR markers were moved synchronously with the 1D
motor-driven base (QUASAR, Modus Medical Devices Inc., London, ON, Canada) in the
anteroposterior (AP) direction.

Dosimetric verification was performed using EDR2 film (Kodak, Rochester, NY,
USA), placed at a depth of 100 mm (1000 mm source-to-isocenter distance) in
water-equivalent phantoms on the motor-driven base. Four pinholes were made on the film to
identify the isocenter. The EDR2 film (Kodak, Rochester, NY, USA) was irradiated with a
field size of 50×50 mm² under stationary, tracking, and non-tracking states for 1D sinusoidal
patterns (A: 20-40 mm, breathing period [T]: 2-4 s) in the craniocaudal (CC) direction. In total,
seven irradiated films were scanned in the same orientation (ES-10000G; Epson Corp., Nagano,
Japan) with a resolution of 150 dpi in 16-bit grayscale with a 12-h postexposure period. All
films were analyzed using commercially available radiation dosimetry software (DD system,
ver. 9.4; R’Tech Inc., Tokyo, Japan). Differences in the width of the 95% dose profile between
stationary and moving conditions ($E_{D}^{95}$) were calculated.

Additionally, positional verification was performed using a laser displacement gauge
(IL-300; Keyence Corp., Osaka, Japan), with a positional accuracy of 0.05 mm. The laser
displacement gauge was used for independent validation of IR Tracking and was not part of the
Vero4DRT IR Tracking system. In the experiment, the target position was measured with the
laser displacement gauge every 10 ms for independent validation, and the laser displacement 165 signals were sent to a system controller for synchronization of the data recording. The Vero4DRT records IR Tracking logs into the system controller every 5 ms. Based on the recorded tracking orientation of the gimbaled x-ray head, the tracked position of the target on the isocenter plane was calculated as follows:

\[ y_t = -960 \tan(\theta_T), \]

where \( y_t \) is the tracked position of the target in the CC direction, \( \theta_T \) is the tilt angle of the gimbaled x-ray head, and 960 mm is the distance from the rotation center of the gimbals to the isocenter. The positional tracking error (\( E_P \)) was defined as \( E_P = y_t - y_{ml} \), where \( y_{ml} \) is the phantom position in the CC direction, measured with the laser displacement gauge. The 95th percentile of the \( E_P \) (\( E_P^{95} \)) was then calculated.

II. B. 2. Positional verification of IR Tracking for 1D phase-shifted sinusoidal patterns

Figure 3(b) shows a photograph of the experimental system for the positional verification of IR Tracking for the 1D phase-shifted sinusoidal patterns (\( A: 20 \text{ mm}, T: 4 \text{ s}, \) phase shift [\( \tau \]): 0.2-2 s):

\[ y_p(t) = 0.5A \sin(\omega t/T), \]
\[ z_s(t) = 0.5A \sin(\omega(t-\tau)/T), \]

where \( y_p(t) \) is the phantom position in the CC direction and \( z_s(t) \) is the displacement of the IR markers in the AP direction. Positional accuracy was evaluated using the dynamic anthropomorphic thorax phantom (CIRS Inc., Norfolk, VA) with a high precision (0.1 mm) laser displacement gauge. \( E_P^{95} \) was estimated as described in Section II. B. 1.

II. B. 3. Positional verification of IR Tracking for 3D respiratory patterns

Figure 3(c) shows a photograph of the experimental system for the positional
verification of IR Tracking with the 3D respiratory patterns acquired from six lung cancer
190 patients. IR markers for measurement using Polaris Spectra (Northern Digital Inc., Waterloo,
Ontario, Canada) and fiducial markers for measurement using the gantry-mounted orthogonal
kV x-ray imaging subsystem were attached to the surface of a cubic phantom. The Polaris
Spectra was used for independent validation of IR Tracking and was not part of the Vero4DRT
IR Tracking system. Then, the cubic phantom was placed firmly on the 3D-driven base of a
four-axis moving phantom, which moved three-dimensionally, based on the acquired internal
target motions. Other IR markers for IR Tracking were also placed on the 1D driven base of the
four-axis moving phantom, which moved based on the acquired IR marker motions in the AP
direction only. The four-axis moving phantom was able to reproduce patient respiratory
motions with high precision (0.1 mm).23 The positions of the IR markers for measurement
200 (P_{mP}[x_{mP}, y_{mP}, z_{mP}]) and fiducial markers for measurement (P_{mX}[x_{mX}, y_{mX}, z_{mX}]) were measured
with the Polaris Spectra, with a measurement accuracy of 0.3 mm, every 16.7 ms, and by the
gantry-mounted orthogonal kV x-ray imaging subsystem every 1 s, respectively. In the present
study, these positional data were recorded synchronously, based on the exposer signal of the
orthogonal kV x-ray imaging subsystem.

First, the detection accuracy of the gantry-mounted orthogonal kV x-ray imaging
subsystem was evaluated in the stationary condition using the treatment couch, with a
positional accuracy of 0.01 mm. Second, in total, 742 comparisons between P_{mP} and P_{mX} were
made to evaluate the detection accuracy of the gantry-mounted orthogonal kV x-ray imaging
subsystem in the moving condition using the Polaris Spectra and the four-axis moving
phantom.

To investigate the tracking accuracy in each direction, positional verification was
performed at gantry angles of 0° and 90°. Based on the recorded tracking orientation of the
gimbaled x-ray head, the tracked position of the target was estimated on the perpendicular
plane to the home gimbal-axis at the measured target position. At a gantry angle of 0°, the tracked position of the target was calculated as follows:

\[ x_t = (960 - z_{mx}) \tan(\theta_p), \]
\[ y_t = -(960 - z_{mx}) \tan(\theta_r), \]

where \( x_t \) is the tracked position of the target in the lateral (LR) direction, \( \theta_p \) is the pan angle of the gimbaled x-ray head, \( y_t \) is the tracked position of the target in the CC direction, and \( \theta_r \) is the tilt angle of the gimbaled x-ray head. At a gantry angle of 0°, the tracked position of the target at the gantry angle of 90° was calculated as follows:

\[ y_t = -(960 - x_{mx}) \tan(\theta_r), \]
\[ z_t = (960 - x_{mx}) \tan(\theta_p), \]

where \( z_t \) is the tracked position of the target in the AP direction. The \( E_p \) was defined as follows:

\[ E_p = \begin{pmatrix} x_t \\ y_t \\ z_t \end{pmatrix} - \begin{pmatrix} x_{mx} \\ y_{mx} \\ z_{mx} \end{pmatrix}. \]

\( E_p^{95} \) was estimated as described in Sections II. B. 1. and II. B. 2.

## III. RESULTS AND DISCUSSION

### III. A. Dosimetric and positional verification of IR Tracking for 1D sinusoidal patterns

Figure 4(a) shows dose profiles of a 50×50-mm² field under stationary, tracking, and non-tracking states for the sinusoidal patterns with \((A, T) = (40 \text{ mm, 2 s})\). The blurred effect, due to phantom motion, was reduced substantially by IR Tracking, comparable with previous results. Figure 4(b) shows variations in the tracked and measured positions of the target for the sinusoidal patterns with \((A, T) = (40 \text{ mm, 2 s})\) in the CC direction. Even for the severe motion
pattern, the gimbaled x-ray head tracked the target in real time with high accuracy.

Table I summarizes $\mu + 2\text{SD}$ of the absolute 4D-modeling error ($E^{\mu+2\text{SD}}_{4DM}$), $E_{D}^{95}$, and $E_{P}^{95}$ of 1D sinusoidal patterns. $E^{\mu+2\text{SD}}_{4DM}$ was calculated from the $\mu$ and SD displayed on the screen of the Vero4DRT in the 4D-modeling phase. Under conditions of perfect correlation between the target and IR marker motions, $E^{\mu+2\text{SD}}_{4DM}$ ranged from 1.4 to 1.9 mm. $E_{D}^{95}$ ranged from 11.2 to 29.6 mm in the non-tracking state; however, these values were reduced by 0.0 to 1.2 mm in the tracking state. IR Tracking reduced blurring dramatically and produced a dose-profile slope similar to that of the stationary state. Additionally, the measured and tracked positions of the target were consistent with each other. $E_{P}^{95}$ ranged from 1.3 to 1.8 mm in the tracking state and from 9.9 to 19.9 mm in the non-tracking state, and $E_{P}^{95}$ in the tracking state was similar to $E^{\mu+2\text{SD}}_{4DM}$. As shown in Table I, $E_{D}^{95}$ was much smaller than twice $E_{P}^{95}$ because the randomized dose errors were partially cancelled out at the field edge; thus, assessment of $E_{P}^{95}$ represents an alternative safety indicator in terms of determining whether the internal margin for IR Tracking is adequate in clinical practice.

III. B. Positional verification of IR Tracking for 1D phase-shifted sinusoidal patterns

Table II summarizes the absolute correlation coefficient between the target and IR marker motions ($|R_{\text{target}}|$), $E^{\mu+2\text{SD}}_{4DM}$, and $E_{P}^{95}$ for phase-shifted sinusoidal patterns. As $|R_{\text{IR}}|$ became small, $E^{\mu+2\text{SD}}_{4DM}$ and $E_{P}^{95}$ increased linearly, from 0.4 to 3.0 mm ($R = -0.98$) and from 0.5 to 2.2 mm ($R = -0.95$), respectively. A strong positive correlation was also found between $E^{\mu+2\text{SD}}_{4DM}$ and $E_{P}^{95}$ ($R = 0.99$). In the 4D-modeling process, the 4D model was created to minimize residual errors between the predicted and detected target positions. Thus, the relationship between $E_{P}^{95}$ and $E_{D}^{95}$ will be almost equivalent even in the presence of a phase shift.
III. C. Positional verification of IR Tracking for 3D respiratory patterns

The root mean squares (RMSs) of the detection accuracy of the gantry-mounted orthogonal kV x-ray imaging subsystem under the stationary condition were 0.07, 0.04, and 0.03 mm in the LR, CC, and AP directions, respectively. The RMSs of the detection accuracy of the gantry-mounted orthogonal kV x-ray imaging subsystem under the moving condition were 0.14, 0.39, and 0.15 mm in the LR, CC, and AP directions, respectively. These results show that the gantry-mounted orthogonal kV x-ray imaging subsystem of the Vero4DRT had high detection accuracy, even for moving targets.

Figure 5 shows variations in the target position along the CC direction for the respiratory pattern of the first patient who underwent IR Tracking (Patient No. 3). $E_p^{95}$ was 1.6 mm for this patient.

Table III summarizes $E_{4DM}^{n+2SD}$ and $E_p^{95}$ for respiratory patterns. A strong negative correlation between $|R_{IR}^{target}|$ and $E_{4DM}^{n+2SD}/A$ was observed in each direction [(LR, CC, AP) = (-0.88, -0.90, -0.92)]. A strong positive correlation was also found between $E_{4DM}^{n+2SD}$ and $E_p^{95}$ in each direction [(LR, CC, AP) = (0.99, 0.98, 1.00)]; thus, $E_p^{95}$ was readily estimated from $E_{4DM}^{n+2SD}$. Figure 6 shows accumulated probability histograms (a) as a function of the positional tracking errors and (b) as a function of the tracking efficiency, defined as the $2E_p^{95}/A$, in each direction at gantry angles of 0° and 90°. The positional tracking errors were larger in the CC direction than in the other directions [Fig. 6(a)]. However, the tracking efficiencies were the highest in the CC direction [Fig. 6(b)]. Lower tracking efficiencies in other directions than in the CC direction were caused by the small $|R_{IR}^{target}|$ (Table III). Additionally, tracking accuracy was not degraded by gantry rotation, even at an angle of 90°.

Pepin et al. suggested that a dry-run treatment session prior to treatment planning is required to determine patient-specific margins covering positional tracking error during the treatment when performing DTT with the Synchrony Respiratory Tracking System.22
present study revealed that positional tracking errors were near-identical to 4D-modeling errors, derived from miscorrelation between the target and abdominal wall motions, such as the phase shift or irregular respiration. Thus, users of the Vero4DRT should evaluate the accuracy of the 4D model in a dry-run treatment session, and the following should then be discussed, based on the acquired 4D-modeling accuracy: (1) adding margins to compensate for 4D-modeling errors and (2) conducting respiratory coaching to minimize the phase shift.24

The correlation between tumor and surrogate motion is known to change from treatment planning to treatment delivery.3,25,26 The change in correlation may cause additional tracking errors in IR Tracking; thus, additional margins to compensate for these uncertainties are required, and confirmation of whether the 4D-modeling errors for each fraction are within the margin derived from 4D-modeling errors at treatment planning is recommended. Additionally, Malinowski et al. reported that an extended treatment time can lead to miscorrelation between the external surrogate and internal tumor motion, due to baseline drift.27 During irradiation, we can estimate visually the tracking errors in real time from the implanted fiducial markers – or the tumor itself – on the intra-fractional fluoroscopic images. When these positions deviate systematically from those predicted, due to baseline drift or changes in respiration, remodeling of the 4D model during a treatment fraction is required to perform IR Tracking safely.

**IV. CONCLUSIONS**

We verified the dosimetric and positional accuracy of IR Tracking and confirmed its feasibility in clinical practice. IR Tracking reduced substantially motion-induced marginal blurring in the dose distribution. Additionally, positional tracking errors correlated strongly with 4D-modeling errors, which resulted from miscorrelations between target and IR marker motions. Thus, the accuracy of the 4D model must be verified before treatment, and margins
are required to compensate for 4D-modeling errors.

ACKNOWLEDGMENTS

The authors express their appreciation to the entire technical staff at MHI for providing detailed information on the gimbaled x-ray head-tracking system and acquiring the experimental data. This research was supported by the Japan Society for the Promotion of Science (JSPS) through its “Funding Program for World-Leading Innovative R&D on Science and Technology (FIRST Program)” and a Grant-in-Aid for Scientific Research from the Association for Nuclear Technology in Medicine.

| 4    | 1.0       | 0.10           | 3.0             | 2.2            |
| 5    | 2.0       | 1.00           | 0.4             | 0.5            |

Abbreviations: $|R_{IR}^{\text{target}}|$ = absolute correlation coefficient between target and IR marker motions; $\mu$ = mean; SD = standard deviation; $E_{4DM}^{\mu+2SD}$ = $\mu$+2SD of the absolute 4D-modeling error; $E_p^{95}$ = 95th percentile of the positional tracking error; $\tau$ = phase shift.
### TABLE III

| Patient no. | $A$ [mm] | $T$ [s] | $|R_{IR}^{target}|$ | $E_{ADM}^{\mu+2SD}$ [mm] | $E_{P}^{95}$ [mm] |
|-------------|---------|---------|----------------|-----------------|-----------------|
|             | LR      | CC      | AP      | LR      | CC      | AP      | LR      | CC      | AP      | LR      | CC      | AP      |
| 1           | 2.4     | 13.9    | 7.5     | 3.6     | 0.78    | 0.91    | 0.01    | 0.6     | 3.0     | 3.2     | 0.7     | 2.9     | 2.6     |
| 2           | 2.0     | 35.2    | 5.6     | 5.5     | 0.41    | 0.99    | 0.93    | 1.0     | 3.3     | 1.4     | 0.9     | 3.6     | 1.2     |
| 3           | 1.7     | 11.9    | 1.5     | 3.4     | 0.98    | 0.98    | 0.26    | 0.2     | 1.3     | 0.5     | 0.2     | 1.5     | 0.6     |
| 4           | 4.2     | 17.0    | 3.4     | 3.5     | 0.92    | 0.99    | 0.93    | 1.2     | 2.5     | 0.4     | 1.2     | 2.6     | 0.5     |
| 5           | 1.7     | 21.2    | 3.3     | 3.4     | 0.97    | 0.98    | 0.92    | 0.3     | 2.4     | 0.5     | 0.3     | 2.4     | 0.6     |
| 6           | 0.7     | 10.7    | 2.6     | 3.1     | 0.17    | 0.99    | 0.60    | 0.3     | 1.0     | 0.7     | 0.3     | 1.0     | 0.8     |

Abbreviations: $|R_{IR}^{target}|$ = absolute correlation coefficient between target and IR marker motions; $\mu$ = mean; SD = standard deviation; $E_{ADM}^{\mu+2SD} = \mu + 2SD$ of the absolute 4D-modeling error; $E_{P}^{95} = 95^{th}$ percentiles of the positional tracking error; $A$ = peak-to-peak amplitude; $T$ = breathing period; LR = lateral direction; CC = craniocaudal direction; AP = anteroposterior direction.
Figure 1

- Infrared camera on ExacTRAC system
- Ring rotation ±60 degree
- Gimbaled x-ray head ±2.5 degree
- Orthogonal kV x-ray imaging subsystem
- Five-axes couch
- Gantry rotation ±185 degree
Figure 2

4D-modeling phase

- Orthogonal kV x-ray tube
- IR camera on ExacTRAC system
- Flat panel detectors
- Orthogonal fluoroscopic images
- Displacements of IR markers

Screen of the Vero4DRT for the 4D-modeling phase

Irradiation phase

- Monitoring IR marker position with IR camera on ExacTRAC
- Calculating 3D target position by 4D model
- Dynamic tumor-tracking
Figure 3a

- IR markers for IR Tracking
- Laser displacement gauge for independent validation
- A film inserted in water eq. phantom
- 1D motor-driven base
