Abstract: Chiral oxacyclic frameworks are prevalent in many natural products and bioactive compounds. In addition, a number of them are important synthetic intermediates. Thus, the synthesis of such structures is a significant goal in the field of organic chemistry. However, the development of catalytic asymmetric cycloetherification for the straightforward synthesis of these compounds remains a challenge. In this study, we propose the use of aminothiourea catalysts as an effective way to accomplish such a challenge. The asymmetric synthesis of chiral oxygen heterocycles, including tetrahydrofurans, tetrahydropyrans, and 1,3-dioxolanes, is demonstrated herein using intramolecular oxy-Michael addition mediated by bifunctional aminothiourea catalysts.

Key words: oxyetherification, cycloetherification, hydrogen bonding, bifunctional aminothiourea catalyst, oxy-Michael addition

Cyclization from unsaturated substrates that bear a pendant nucleophilic oxygen atom is a straightforward way to synthesize chiral oxacyclic compounds. However, asymmetric cycloetherification reactions are highly challenging because of the difficulty in installing a suitable chiral environment during the rapid intramolecular process. On the other hand, several asymmetric oxyetherifications have successfully been developed, including enantioselective intramolecular aza-Michael additions using a proline-derived catalyst or a chiral phase-transfer-catalyst. The enantioselective of these azacyclizations was largely controlled by the effects of the substituents on the nucleophilic nitrogen atom through steric repulsion or π-interactions. Meanwhile, because such a substituent is lacking in the oxyetherification substrates, those strategies can only be applied to starting materials that bear an appropriate substituent in the vicinity of the alcohol. Therefore, a novel strategy is required to obtain an efficient asymmetric oxyetherification reaction. In this context, hydrogen bonding is an interaction with the potential to be able to control the behavior of a pendant OH group (Scheme 1). Thus, the use of organocatalysts that utilize hydrogen bonding is a promising approach to realizing enantioselective oxyetherification. Moreover, multipoint recognition by an asymmetric catalyst would be favorable for the achievement of effective transfer of the chiral information during the cyclization process (Scheme 1).

Evidence for the validity of this concept can be found in some recent reports on catalytic asymmetric halolactonizations using bifunctional organocatalysts. These allow multipoint interactions in the reaction transition states, one of which is hydrogen bonding with the pendant carboxyl group. In addition, a number of other highly enantioselective oxyetherifications using organocatalysts have been developed, where hydrogen bonding is thought to have played a role in controlling the chirality. However, whereas an increasing number of methods for asymmetric cyclolactonizations have recently been reported, examples of cycloetherifications are still limited. In particular, catalytic enantioselective cycloetherifications are extremely challenging because of the higher nucleophilicity of hydroxyl groups compared to carboxyl groups. In fact, several of the previously reported cycloetherifications demonstrated only moderate enantioselectivity, resulting from background racemic reactions that occurred, even at low temperatures. They therefore required a stoichiometric or extremely high loading of chiral mediators in order to achieve acceptable selectivity. To overcome such drawbacks, we developed an intramolecular oxy-Michael addition reaction by employing bifunctional aminothiourea catalysts that utilize hydrogen bonding at both catalytic sites. It was hypothesized that the mild character of hydrogen bonding would facilitate concerted catalysis through multipoint recognition, even with highly reactive substrates, for cycloetherification (Scheme 2).

Scheme 1 Strategies for asymmetric aza- and oxyetherifications.

(PG: protecting group)
Herein, we describe a highly enantioselective catalytic cycloetherification for the synthesis of 2-substituted tetrahydrofurans (Table 1) and tetrahydropyrans (Table 2). An intramolecular oxy-Michael addition reaction from ε- or ω-hydroxy-α,β-unsaturated ketones could be performed in a highly enantioselective fashion by using cinchona-alkaloid-thiourea-based bifunctional organocatalyst 3a (Figure 1). Screening of the catalysts shown in Figure 1 further demonstrated that 3c is an efficient catalyst for obtaining the opposite enantiomer ent-2a in excellent yield with high enantioselectivity (Table 1, entry 2). Moreover, the catalytic loading could be decreased to as low as 1 mol % in the THF synthesis, while still giving excellent enantioselectivity (Table 1, entry 3). This catalytic process is a highly practical cycloetherification method that provides excellent enantioselectivities, even with low catalyst loadings at ambient temperature. Although the reactions were slower, a similar reaction condition also led to the highly enantioselective synthesis of 2-substituted tetrahydropyrans (Table 2).

* Reaction was run for 120 h.

The obtained THF product 2b could be further transformed into the corresponding ester 6 by means of Baeyer–Villiger oxidation with m-CPBA in the presence of TFA in 92% yield without any loss of optical purity (Scheme 3). Subsequent reduction of 6 with lithium aluminum hydride afforded (R)-2-(tetrahydrofuran-2-yl)ethanol (7), which is a valuable synthetic intermediate (Scheme 3).

Scheme 3 Transformation of 2b.

These results subsequently motivated us to exploit this efficient oxy cyclization protocol for the development of a catalytic formal [3+2] cycloaddition reaction starting from γ-hydroxy-α,β-unsaturated carboxyls16 with aldehydes or ketones (Scheme 4). This method led to the successful divergent synthesis of chiral 1,3-dioxolanes.17 In this reaction, the hemiacetal intermediate generated in situ was the substrate for the cycloetherification mediated by chiral amino thiourea.18,19
The utility of the products as synthetic intermediates was demonstrated by performing the transformation of 10aa. Reduction with lithium aluminum hydride in the presence of lithium iodide afforded the corresponding alcohol 11 with high diastereoselectivity, and subsequent de-acetalization gave optically active triol 12 (Scheme 5). In addition, treatment of 10aa with allyltrimethylsilane in the presence of titanium tetrachloride led to allylative ring cleavage to provide 13 in a regio- and diastereoselective fashion while maintaining the optical purity (Scheme 6).

To gain further insight into the enantio-determining step, formal [3+2] cycloaddition reactions were investigated using formaldehyde (9f) and acetone (9g) with 8a (Scheme 7). It was found that products 10af and 10ag were obtained enantioselectively, regardless of the achirality of the forming acetal carbon. These results strongly suggest that the intramolecular oxy-Michael addition from the hemiacetal intermediates proceeded with high enantioselectivity according to our original hypothesis. This is also in agreement with the consistent absolute configuration (the same (S)-configuration) at the β-position of the carbonyl group in both diastereomers of 10da (Scheme 8).

Considering these stereochemical outcomes, although the diastereoselectivity was only moderate, these reactions can be recognized as a way to achieve highly enantioselective oxygen atom introduction at the β-position of the carbonyl group. This cyclization protocol was therefore applied to reactions using carboxylic acid derivatives as substrates. There have been very few demonstrations of asymmetric oxy-Michael additions to high oxidation state substrates, such as α,β-unsaturated carboxylic acid derivatives, despite their great synthetic importance.

By employing studies involving the optimization of substrates and reaction conditions, 2,6-

**Scheme 4** Chiral 1,3-dioxolane synthesis via asymmetric cycloetherification using a bifunctional aminothiourea catalyst.

Employing the conditions described in Table 3, various 1,3-dioxolanes were stereoselectively obtained by the formal cycloaddition reaction using 3a as a catalyst. In addition, catalyst screening identified 3c as an efficient catalyst for obtaining the opposite enantiomer ent-10aa in good yield with high enantioselectivity (Table 3, entry 2).

![Scheme 5](image3)

**Scheme 5** Synthesis of chiral triol 12.

Scheme 6 Stereospecific ring cleavage of 10aa.

![Scheme 6](image4)

**Scheme 6** Stereospecific ring cleavage of 10aa.

The utility of the products as synthetic intermediates was demonstrated by performing the transformation of 10aa. Reduction with lithium aluminum hydride in the presence of lithium iodide afforded the corresponding alcohol 11 with high diastereoselectivity, and subsequent de-acetalization gave optically active triol 12 (Scheme 5). In addition, treatment of 10aa with allyltrimethylsilane in the presence of titanium tetrachloride led to allylative ring cleavage to provide 13 in a regio- and diastereoselective fashion while maintaining the optical purity (Scheme 6).
dimethylbenzenethiol ester 14 was identified as the best substrate, and pivaldehyde (9d) proved to be a good counterpart. The reaction between these components, using 3a as a catalyst, gave a diastereomer mixture of the desired products (15 and 15’) in high yield, with excellent enantioselectivity for both diastereomers (Scheme 9).24 Stereochemical analysis of the products revealed that these diastereomers had the same (S)-configuration at the β-position of the carbonyl group as was expected.25

The easily removable acetal functionality enables this oxy-Michael addition method to be useful as an enantioselective formal hydration.26 In order to demonstrate this, the obtained products were further extended to the asymmetric syntheses of some β-hydroxy carboxyl compounds (Scheme 10). Treatment of the diastereomer mixture of 15 and 15’ with titanium tetrachloride led to the generation of free β,γ-dihydroxy compound 16 with high optical purity, while keeping the thioester group intact. Alternatively, treatment of the diastereomer mixture with p-toluenesulfonic acid in an aqueous medium gave β-hydroxy-γ-butyrolactone 17, a versatile chiral synthetic intermediate,27 which could be transformed into (L)-carnitine (18), an important bioactive agent, using a previously reported procedure.28

![Scheme 9](image1)

Scheme 9 Asymmetric oxy-Michael addition to γ-hydroxy-α,β-unsaturated thioester 14.

15, and it was found that the chiral acetal moiety was unchanged after the transformations (Scheme 11). Reduction of 15 with lithium aluminium hydride afforded the corresponding primary alcohol 19 quantitatively, without any erosion of optical purity. In addition, Liebeskind–Srogl cross coupling enabled the replacement of the arylthio group of 15 to give ketone 10ad,29 indicating that these thioester products can be easily transformed into a wide variety of chiral compounds.

![Scheme 11](image2)

Scheme 11 Transformations of the thioester group of 15.

In summary, we have demonstrated asymmetric intramolecular oxy-Michael addition reactions using cinchona-alkaloid-thiourea-based bifunctional organocatalysts. The developed methods afforded several important oxacyclic compounds, including tetrahydrofurans, tetrahydropryan, and 1,3-dioxolanes. A number of the resulting products were demonstrated to be useful synthetic intermediates that could be further transformed into valuable bioactive compounds. This study indicates that the approach based on the use of hydrogen bonding is an effective way to achieve enantioselective cycloetherification. Further studies on the application of this methodology to the synthesis of other chiral oxygen heterocycles are currently underway in our laboratory and will be reported in due course.

1H and 13C Nuclear magnetic resonance spectra were taken on a Varian UNITY INOVA 500 (1H, 500 MHz; 13C, 125.7 MHz) spectrometer using tetramethylsilane as an internal standard for 1H NMR (δ = 0 ppm) and CDCl3 as an internal standard for 13C NMR (δ = 77.0 ppm). When a 13C NMR spectrum was measured using C6D6 as a solvent, C6D6 was used as an internal standard (δ = 128.06 ppm). 1H NMR data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, quint = quintet, sext = sextet, sept = septet, br = broad, m = multiplet), coupling constants (Hz), integration. 19F NMR spectra were measured on a Varian Mercury 200 (19F, 188 MHz) spectrometer with hexafluorobenzene as an internal standard (δ = 0 ppm). GC-MS analyses and High-resolution mass spectra were obtained with
a JEOL JMS-700 spectrometer by electron ionization at 70 eV. High performance liquid chromatography (HPLC) was performed with a SHIMADZU Prominence. Infrared (IR) spectra were determined on a SHIMADZU IR Affinity-1 spectrometer. Melting points were determined using a YANAKO MP-500D. Optical rotations were measured on a HORIBA SEPA-200. X-ray data were taken on a Bruker Smart APEX X-Ray diffractometer equipped with a large area CCD detector. The structures were solved with the program system SHELXS-97 and refined with SHELXL-97 package from Bruker. TLC analyses were performed by means of Merck Kieselgel 60 F254 (0.25 mm) Plates. Visualization was accomplished with UV light (254 nm) and/or such as an aqueous alkaline KMnO4 solution followed by heating.

Flash column chromatography was carried out using Kanto Chemical silica gel (spherical, 40–50 μm). Unless otherwise noted, commercially available reagents were used without purification.

**General procedure for preparation of bifunctional aminothiourea catalysts 3**

Bifunctional organocatalysts 3 were prepared by the literature procedure.\(^3\)\(^{1-3}\) A cinchona alkaloid (5 mmol) and triphenylphosphine (1.6 g, 6 mmol) were dissolved in THF (25 mL), and the solution was cooled to 0 °C. Diethyl azodicarboxylate (1.0 g, 6 mmol) was subsequently added. To the resulting solution was added dropwise the solution of diphenyl carbonate (25 mL) at ambient temperature. H2O (0.5 mL) was added, and the solution was stirred for 24 h. The solvents were removed in vacuo, and the residue was dissolved in CH2Cl2/10% aqueous hydrochloric acid (25 mL/25 mL). The aqueous phase was separated and washed with CH2Cl2 (25 mL x 4). It was subsequently made alkaline with aqueous ammonia, and the aqueous phase was extracted with CH2Cl2 (25 mL x 4). The combined organic layers were dried over Na2SO4 and concentrated in vacuo. Purification by flash silica gel column chromatography using EtOAc/CH2Cl2 (v/v= 9/1) then CHCl3/CH2Cl2 (v/v= 8/2) as an eluent gave the corresponding 9-amino(9-deoxy)cinchona alkaloids. Next, to the solution of the obtained 9-amino(9-deoxy)cinchona alkaloid in THF (6 mL) was slowly added a solution of 3,5-bis(trifluoromethyl)phenyl isothiocyanate (1 equiv) in THF (4 mL) at ambient temperature. The mixture was stirred overnight, and the solvents were removed in vacuo. Purification by flash silica gel column chromatography using EtOAc/CH2Cl2 (v/v= 95/5–97.5/2.5) or EtOAc as an eluent gave the corresponding bifunctional organocatalyst 3.

3d. White solid; 44% yield (1.2 g) (for 2 steps from cinchonidine). |α|D23 +101.0 (c 1.24, CH2Cl2). 1H NMR (CDCl3) δ 8.80 (br s, 1H), 8.35 (br s, 1H), 8.14 (d, J = 8.5 Hz, 1H), 7.80 (s, 2H), 7.74 (dd, J = 8.0, 7.5 Hz, 1H), 7.69 (s, 1H), 7.63 (dd, J = 8.0, 7.5 Hz, 1H), 7.27 (br s, 1H), 5.78 (br s, 1H), 5.67 (m, 1H), 4.98 (m, 2H), 3.26 (m, 1H), 3.20 (br s, 1H), 3.17 (dd, J = 13.5, 10.5 Hz, 1H), 2.78 (m, 2H), 2.53 (br s, 1H), 1.70 (m, 2H), 1.63 (m, 1H), 1.33 (m, 1H), 0.93 (br s, 1H). 13C NMR (CDCl3) δ 180.9, 149.9, 148.5, 145.9, 140.7, 139.9, 132.6 (q, J = 33.6 Hz), 130.4, 129.5, 127.0, 123.6, 122.9 (q, J = 273.0 Hz), 119.1, 118.9, 115.0, 61.5, 56.5, 54.9, 41.1, 39.2, 27.5, 27.1, 25.7. Mp. 122.8–123.1 °C. IR (neat): 3240, 3081, 2946, 2366, 1510, 1473, 1384, 1281, 1181, 1135, 990, 958, 884, 849, 755, 683 cm⁻¹. HRMS Calcd for C38H32F6N8S: [M+H]+, 565.1861. Found: mlc/z 565.1855.

General procedure for asymmetric synthesis of 2-substituted tetrahydrofurans 2

In a 5-mL vial, we sequentially added ε-hydroxy-α,β-unsaturated ketone 1 (0.25 mmol), cyclopentyl methyl ether (CPME, 0.5 mL), and quinidine-derived bifunctional catalyst 3a (0.0075 mmol). The mixture was stirred in an oil bath maintained at 25 °C for 24 h. The reaction mixture was subsequently diluted with hexane/EtOAc (v/v = 1/1), passed through a short silica gel pad to remove 3a, and concentrated in vacuo. Purification of the reaction mixture by flash silica gel column chromatography using hexane/EtOAc (v/v = 3/1) as an eluent afforded the corresponding 2-substituted tetrahydrofuran 2.

1-Phenyl-2-(tetrahydro-2H-pyran-2-yl)ethanone (5a).

Yield: 90% (27.1 mg), 91% ee, colorless oil. |α|D25 +16.8 (c 2.53, CH2Cl2). 1H NMR (CDCl3) δ 7.97 (m, 2H), 7.56 (m, 1H), 7.46 (m, 2H), 3.96 (m, 2H), 3.48 (m, 1H), 3.29 (dd, J = 16.0, 6.5 Hz, 1H), 2.92 (dd, J = 16.0, 5.5 Hz, 1H), 1.84 (m, 1H), 1.75 (m, 1H), 1.57 (m, 2H), 1.52 (m, 1H), 1.36 (m, 1H). 13C NMR (CDCl3) δ 198.4, 137.4, 133.0, 128.5, 128.3, 74.4, 68.7, 45.4, 32.0, 25.9, 23.4. TLC: Rf 0.45 (hexane/EtOAc = 3:1). IR (neat): 3060, 2936, 2849, 1686, 1597, 1581, 1449, 1379, 1357, 1325, 1292, 1273, 1208, 1194, 1175, 1088, 1045, 1003, 971, 904, 810, 777, 751, 692, 661, 471 cm⁻¹. HRMS Calcd for C13H17O2: [M+H]+, 205.1229. Found: mlc/z 205.1227.

1-(4-Methoxyphenyl)-2-(tetrahydro-2H-pyran-2-yl)ethanone (5b).

Yield: 56% (19.7 mg), 94% ee, colorless oil. |α|D25 +20.8 (c 1.97, CH2Cl2). 1H NMR (CDCl3) δ 7.95 (m, 2H), 6.91 (m, 2H), 3.95 (m, 1H), 3.93 (m, 1H), 3.86 (s, 3H), 3.47 (m, 1H), 3.23 (dd, J = 16.0, 7.0 Hz, 1H), 2.86 (dd, J = 16.0, 6.0 Hz, 1H), 1.83 (m, 1H), 1.73 (m, 1H), 1.59–1.49 (m, 3H), 1.34 (m, 1H). 13C NMR (CDCl3) δ 196.9, 163.4, 130.5, 130.1, 113.6, 74.4, 68.6, 54.5, 45.0, 32.0, 25.8, 23.3. TLC: Rf 0.29 (hexane/EtOAc = 3:1). IR (neat): 2934, 2844, 1672, 1600, 1577, 1510, 1309, 1261, 1170, 1087, 1045, 1031, 843, 450 cm⁻¹. HRMS Calcd for C13H13O2: [M+H]+, 235.1329. Found: mlc/z 235.1377.

1-(4-Trifluoromethylphenyl)-2-(tetrahydro-2H-pyran-2-yl)ethanone (5c).

Reaction was run on 0.1 mmolscale.

Yield: 95% (25.9 mg), 85% ee, white solid. |α|D25 +3.86 (c 2.59, CH2Cl2). 1H NMR (CDCl3) δ 8.06 (m, 2H), 7.72 (m, 2H), 3.95 (m, 1H), 3.93 (m, 1H), 3.50 (m, 1H), 3.30 (dd, J = 16.0, 7.0 Hz, 1H), 2.90 (dd, J = 16.0, 5.0 Hz, 1H), 1.85 (m, 1H), 1.73 (m, 1H), 1.59 (m, 1H), 1.55 (m, 1H), 1.52 (m, 1H), 1.39 (m, 1H). 13C NMR (CDCl3) δ 197.6, 139.9, 134.2 (q, J = 32.7 Hz), 128.6, 125.6 (q, J = 3.9), 123.5 (q, J = 272.6 Hz), 74.2, 68.6, 45.6, 31.9, 25.7, 23.3. 19F NMR (CDCl3) δ 98.7. Mp. 51.5–52.5 °C. TLC: Rf 0.49 (hexane/EtOAc = 3:1). IR (KBr): 2946, 2936, 2925, 2857, 1681, 1412, 1334, 1323, 1213, 1170, 1158, 1134, 1124, 1113, 1107, 1084, 1070, 1006, 848, 829 cm⁻¹. HRMS Calcd for C13H13F2O: [M+H]+, 273.1097. Found: mlc/z 273.1106.

1-(Naphthalen-2-yl)-2-(tetrahydro-2H-pyran-2-yl)ethanone (5d).

Yield: 80% (30.5 mg), 94% ee, colorless oil. |α|D25 +26.7 (c 3.05, CH2Cl2). 1H NMR (CDCl3) δ 8.49 (m, 1H), 8.04 (m, 1H), 7.96 (d, J = 8.5 Hz, 1H), 7.88 (m, 2H), 7.58 (m, 1H), 7.55 (m, 1H), 4.02 (m, 1H), 3.96 (m, 1H), 3.51 (m, 1H), 3.45 (dd, J = 16.0, 6.5 Hz, 1H), 3.05 (dd, J = 16.0, 5.5 Hz, 1H), 1.86 (m, 1H), 1.78 (m,
1H, 1.62–1.55 (m, 2H), 1.51 (m, 1H), 1.41 (m, 1H). 13C NMR (CDCl3) δ 198.3, 135.5, 134.5, 132.4, 130.1, 129.6, 128.43, 128.36, 127.7, 126.7, 123.9, 74.4, 68.6, 45.4, 3.20, 25.8, 23.4. TLC: Rf 0.36 (hexane/EtOAc = 3:1). IR (neat): 3508, 2935, 2848, 2739, 2667, 2314, 1680, 1636, 1469, 1387, 1355, 1295, 1209, 1087, 863, 821, 747, 677, 450 cm\(^{-1}\). HRMS calcd for C\(_7\)H\(_7\)O: [M+H]*: 255.1380. Found: m/z 255.1388.

1-(4-Methylphenyl)-2-(tetrahydro-2H-pyran-2-yl)ethanone (5e).

Yield: 76% (24.9 mg). 94% ee, colorless oil. \([\alpha]_D^{25}\) +14.9 (c 2.49, CH\(_2\)Cl\(_2\)). 1H NMR (CDCl3) δ 7.86 (m, 2H), 7.26 (m, 2H), 3.95 (m, 1H), 3.93 (m, 1H), 3.47 (m, 1H), 3.23 (dd, J = 16.0, 6.0 Hz, 1H), 2.90 (dd, J = 16.0, 6.0 Hz, 1H), 2.40 (s, 3H), 1.83 (m, 1H), 1.74 (m, 1H), 1.58 (m, 1H), 1.54 (m, 1H), 1.49 (m, 1H), 1.35 (m, 1H). 13C NMR (CDCl3) 198.0, 143.8, 134.7, 129.2, 128.4, 74.4, 68.6, 45.2, 32.0, 25.8, 23.4, 21.6. TLC: Rf 0.44 (hexane/EtOAc = 3:1). IR (neat): 2933, 2853, 2360, 2331, 1686, 1607, 1087, 1045, 971, 475, 448 cm\(^{-1}\). HRMS calcd for C\(_8\)H\(_8\)O: [M+H]*, 219.1380. Found: m/z 219.1389.

1-(4-Bromophenyl)-2-(tetrahydro-2H-pyran-2-yl)ethanone (5f).

Yield: 99% (42.1 mg). 94% ee, white solid. \([\alpha]_D^{25}\) +10.9 (c 4.21, CH\(_2\)Cl\(_2\)). 1H NMR (CDCl3) δ 7.81 (m, 2H), 7.56 (m, 2H), 3.92 (m, 1H), 3.90 (m, 1H), 3.41 (m, 1H), 3.22 (dd, J = 16.0, 7.0 Hz, 1H), 2.83 (dd, J = 16.0, 5.5 Hz, 1H), 1.79 (m, 1H), 1.70 (m, 1H), 1.59–1.52 (m, 2H), 1.48 (m, 1H), 1.35 (m, 1H). 13C NMR (CDCl3) δ 197.4, 135.8, 131.7, 129.7, 124.2, 68.5, 45.2, 31.9, 25.7, 23.3. Mp: 55.3–55.5 °C. TLC: Rf 0.49 (hexane/EtOAc = 3:1). IR (KBr): 2960, 2937, 2924, 2845, 1684, 1584, 1400, 1207, 1087, 1072, 999, 973, 835, 807 cm\(^{-1}\). HRMS calcd for C\(_{13}\)H\(_{16}\)BrO: [M+H]*, 283.0328. Found: m/z 283.0339.

HPLC (Daicel Chiralpak AD-H, hexane/EtOAc = 98.5/1.5) afforded the corresponding 1,3-dioxolanes 10.

General procedure for asymmetric synthesis of 1,3-dioxolanes 10

In a 5-mL vial, we sequentially added γ-hydroxy-α,β-unsaturated ketone 8 (0.25 mmol), cyclopentyl methyl ether (CPME, 0.5 mL), aldehyde or ketone 9 (0.3 mmol), and quinidine-derived bifunctional catalyst 3a (0.025 mmol). The mixture was stirred in an oil bath maintained at 25 °C for 24 h. The reaction mixture was sequentially diluted with hexane/EtOAc (v/v = 1/1), passed through a short silica gel pad to remove 3a, and concentrated in vacuo. Purification of the reaction mixture by flash silica gel column chromatography using hexane/EtOAc (v/v = 10/1) as an eluent afforded the corresponding 1,3-dioxolane 3 as a mixture of the diastereomers. In most cases, the diastereomers were further separated by flash silica gel column chromatography (see ref 20 for details).

Proced for asymmetric oxy-Michael addition reaction to γ-hydroxy-α,β-unsaturated thioester 14

In a 5-mL vial, we sequentially added γ-hydroxy-α,β-unsaturated thioester 14 (0.20 mmol), cyclopentyl methyl ether (CPME, 2.0 mL), pivaldehyde (9d, 4.0 mmol), and quinidine-derived bifunctional catalyst 3a (0.26 mmol). The mixture was stirred in an oil bath maintained at 25 °C for 48 h. The reaction mixture was sequentially diluted with hexane/EtOAc (v/v = 1/1), passed through a short silica gel pad to remove 3a, and concentrated in vacuo. Purification of the reaction mixture by flash silica gel column chromatography using hexane/EtOAc (v/v = 10/1) as an eluent afforded the corresponding oxy-Michael adducts 15 and 15′ as a mixture of the diastereomers.

See ref 14, 20, and 24 for further details on the experimental procedures and the characterization data of compounds.
