17 Abstract:

18 Previous study showed that tetraploid wheat was divided into two groups (Type AI and Type

19 AII) based on sequences around *Ppd-A1* gene (Takenaka and Kawahara 2012). That study focused on
20 domesticated emmer wheat and used only 19 wild emmer wheat, so could not be clear the evolutional
21 relationship between Type AI and Type AII. Here, a total of 669 accessions comprising 65 einkorn wheat,
22 185 wild emmer wheat, 107 hulled emmer wheat, 204 free-threshing (FT) emmer wheat, and 108
23 timopheevii wheat were studied by PCR assay and DNA sequencing for Type AI/AII. Type AII was an
24 older type than Type AI because all einkorn accessions had Type AII. In wild emmer, Type AI was
25 distributed in the northeast regions of its distribution and Type AII was found to be centered on Israel. A
26 total of 37.4% of hulled emmer accessions were Type AI, while 92.2% of FT emmer accessions were
27 Type AI. Differences in the proportion of Type AI/AII in domesticated emmer suggested a strong
28 bottle-neck effect. We also found two MITE-like sequence deletion patterns from a part of Type AII
29 accessions (dic-del and ara-del). Dic-del was found from only Israeli wild emmer accessions and ara-del
30 was found from almost all timopheevii wheat accessions. Only three timopheevii accessions did not have
31 ara-del, and one wild emmer accession and ten hulled emmer accessions had ara-del. These accessions
32 suggested gene flow between emmer and timopheevii wheat.

33 Key Words:

34 tetraploid wheat, Ppd-1, domestication, evolution, gene flow

35

1 Introduction

2 Wheat is the one of the most important staple crops and is cultivated all over the world. Today,
3 it accounts for more than 20% of total human food calories (faostat.fao.org). There is an urgent need to
4 improve wheat for sustainable production in response to an explosion in world population and global
5 climate change (wheat.org). For wheat breeding to satisfy such requirements, the genetic diversity of wild
6 relatives and wheat landraces adapting to various environment is very important as genetic resources
7 (Harlan 1975).

8 The genus *Triticum* L. consists of diploid einkorn wheat ($2n = 14$, AA), tetraploid emmer ($2n =$
9 28 , BBA^uA^u) and timopheevii wheats (GGA^uA^u), and hexaploid common wheat ($2n = 42$, DDBBA^uA^u)
10 (for a review, see Lilienfeld 1951). Tetraploid wheats originated independently by hybridization and
11 amphiploidization between *Aegilops speltoides* (SS) (or a genotype similar to it) as the female parent and
12 *T. urartu* (A^uA^u) as the male parent (Hori and Tsunewaki 1967; Maan and Lucken 1971; Ogiara and
13 Tsunewaki 1982; Dvořák *et al.* 1993; Tsunewaki 2009). The hybridization that generated wild emmer
14 wheat (*T. dicoccoides*) may have occurred between 0.25 to 1.3 Mya ago (Mori *et al.* 1995; Huang *et al.*
15 2002), while the hybridization that led to wild timopheevii wheat (*T. araraticum*) is likely to have
16 occurred later (Mori *et al.* 1995; Brown-Guedira *et al.* 1996; Rodriguez, Perera *et al.* 2000; Huang *et al.*
17 2002; Kilian *et al.* 2007). Wild emmer wheat was domesticated in the Levant (southeastern Turkey to
18 Syria) about 10,000 years before present (BP) (Nesbitt and Samuel 1998; Özkan *et al.* 2002, 2005; Mori
19 *et al.* 2003; Tanno and Willcox 2006; Luo *et al.* 2007; Dubcovsky and Dvorak 2007). As an important
20 component of the West Asian agriculture complex, domesticated hulled emmer (*T. dicoccum* etc.) spread
21 throughout the world (Bellwood 2005; Luo *et al.* 2007). By about 8,500 years BP, hulled emmer wheat
22 with tough glumes had evolved to free-threshing (FT) emmer wheat (*T. durum* etc.) (Salamini *et al.* 2002).
23 Wild timopheevii wheat was also domesticated in southern Turkey and northern Syria (Mori *et al.* 2009).

24 However, unlike emmer wheat, domesticated timopheevii wheat (*T. timopheevii*) is an endemic crop
25 restricted to western Georgia in Transcaucasia (Zohary and Hopf 2000).

26 Our previous study shows that emmer wheat is divided into two groups (Type AI and Type AII)
27 based on about 200 bp sequences, which are around 1 kbp upstream of the *Ppd-A1* gene and include
28 insertion/deletion mutations (Fig. 1, Takenaka and Kawahara 2012). Some hulled emmer wheat of Type
29 AII are devoid of about 100 bp of MITE-like sequences (Type AIIa). They also report that in
30 domesticated emmer, less than half of hulled emmer (44.4%) are Type AI and most FT emmer (94.7%)
31 are Type AI and Type AII FT emmer are restricted to former Yugoslavian countries, while in wild emmer,
32 Type AI are distributed in Turkey, Iran, Iraq, and Israel and Type AII are distributed in Israel, Syria, and
33 Turkey. That study focused on domesticated emmer and used only 19 wild emmer accessions, so could
34 not clarify the evolution of emmer wheat. In this paper, we focus on the regions dividing Type AI and
35 Type AII, and the deletion pattern of MITE-like sequences. We also discuss the evolution of tetraploid
36 wheats using more wheat accessions than the previous study.

37

38 Materials and Methods

39 Plant Materials

40 A total of 669 accessions of wheat comprising 185 wild emmer wheat (*Triticum dicoccoides*
41 (Körn. ex Asch. et Graebn.) Schweinf.), 107 domesticated hulled emmer wheat (*T. dicoccum* Schrank, *T.*
42 *karamyschevii* Nevski and *T. ispahanicum* Heslot), 204 domesticated free-threshing (FT) emmer wheat (*T.*
43 *durum* Desf., *T. turgidum* L. s. str., *T. polonicum* L., *T. carthlicum* Nevski, *T. turanicum* Jakubz., *T.*
44 *aethiopicum* Jakubz. and *T. pyramidale* (Del.) Perc.), 103 wild timopheevii wheat (*T. araraticum* Jakubz.),
45 5 domesticated timopheevii wheat (*T. timopheevii* (Zhuk.) Zhuk. s. str.), 60 wild einkorn wheat (*T.*
46 *boeoticum* Boiss. and *T. urartu* Thum. ex Gandil.), and 5 domesticated einkorn wheat (*T. monococcum* L.)

47 were used (Table S). A total of 158 accessions had been analyzed by Takenaka and Kawahara (2012), of
48 which 19 were wild emmer wheat accessions, 45 hulled emmer wheat accessions, and 94 FT emmer
49 wheat accessions. Sixty-seven wild emmer accessions had been analyzed by Özkan *et al.* (2011). These
50 accessions were maintained at National BioResources Project KOMUGI (Laboratory of Crop Evolution,
51 Graduate School of Agriculture, Kyoto University) and USDA. Seeds of 12 wild *timopheevii* accessions
52 were kindly provided by Dr. Sasanuma, Yamagata University, Japan and Dr. Mori, Kobe University, Japan.
53 In this paper, the nomenclature and genome formula is followed from Hammer *et al.* (2011) and the
54 Catalogue of NBRP KOMUGI with little changes.

55

56 PCR assays for Type AI and Type AII

57 Total DNA was extracted from young leaves from each accession by the CTAB method
58 (Escaravage *et al.* 1998). Extracted DNA was stored in 100 µL of TE buffer at 4°C. DNA was amplified
59 by PCR using specific primers for Type AI and Type AII, which corresponded to Type AI and Type AII
60 and produced a band (Takenaka and Kawahara 2012). PCR amplification involved 50 ng of template
61 DNA, 1 µM each primer, 1.5 mM MgCl₂, 0.2 mM dNTPs, 1.5 µL of 10×PCR Buffer (TaKaRa, Japan),
62 and 0.5 U of *Taq* Polymerase (TaKaRa, Japan) in a total volume of 15 µL. Amplification conditions were
63 96°C for 2 min followed by 30 cycles of 96°C for 20 sec, 62°C for 20 sec, and 72°C for 30 sec. PCR
64 products were separated on 2% agarose gels in TAE buffer.

65

66 DNA Sequencing

67 All accessions that were divided into Type AIIa by PCR assays were sequenced and the
68 deletion pattern of MITE-like sequences was checked. PCR amplification involved 50 ng of template
69 DNA, 1 µM each primer (up_A_F9: aacaacgagcatggacgagac, up_A_R600: ctggatccgcataatctttctc), 0.2 mM

70 dNTPs, 2 µL of 10×*Ex Taq* Buffer (TaKaRa, Japan), 0.6 µL of DMSO, and 0.5 U of *TaKaRa Ex Taq HS*
71 (TaKaRa, Japan) in a total volume of 20 µL. Amplification conditions were 30 cycles of 98°C for 10 s,
72 62°C for 15 s, and 72°C for 2 min. PCR products were cleaned using the AMPure® kit (Bio Medical
73 Science, Tokyo, Japan). The BigDye Terminator v3.1 Cycle Sequencing® kit (Applied Biosystem, Tokyo,
74 Japan) and a primer (up_A_R601: cgcataatctttctcctctcc) were used for sequencing reactions. Sequencing
75 reaction products were cleaned using CleanSEQ® (Applied Biosystem, Tokyo, Japan) and sequenced
76 using an ABI PRISM® 3100 Genetic Analyzer. The primers used for PCR amplification and sequencing,
77 designed for use with primer 3 (Rozen and Skaletsky 2000), were based on sequence data from the DDBJ
78 website (<http://www.ddbj.nig.ac.jp/>). The sequence data from *Ppd-A1*, *Ppd-B1*, and *Ppd-G1* and their
79 adjacent regions were obtained from a total of 77 accessions (5 wild emmer wheat, 9 hulled emmer wheat,
80 2 FT emmer wheat, 10 wild timopheevii wheat, 5 domesticated timopheevii wheat, 43 wild einkorn wheat,
81 and 3 domesticated einkorn wheat, table S) according to a previous study (Takenaka and Kawahara 2012).

82

83 Data analyses

84 Sequences were manually inspected with BioEdit ver. 7.0.9 (Hall 1999) and alignments were
85 generated with MAFFT v6.846b (Kato and Toh 2008). The sequence data from 5' UTR, intronic, coding,
86 and 3' UTR regions of *Ppd-A1* and intronic and coding regions of *Ppd-B1* and *Ppd-G1* were analyzed for
87 phylogenetic relationships by the neighbor-joining (NJ) method (Saitou and Nei 1987) using MEGA ver.
88 5.0 (Tamura *et al.* 2011). Evolutionary distances were computed using the Kimura 2-parameter method
89 (Kimura 1980) and all positions containing alignment gaps and missing data were eliminated only in
90 pairwise sequence comparisons. The percentage of replicate trees in which associated haplotypes
91 clustered together was calculated in the bootstrap test (1,000 replicates). Haplotypes based on sequencing
92 data of *Ppd-1* genes (coding and intronic regions) were scored with DnaSP ver. 5.1 (Librado and Rozas

93 2009) and Median-Joining (MJ) networks (Bandelt *et al.* 1999) were constructed with the Network 4.610
94 program (Fluxus Technology Ltd, Clare, Suffolk, UK). GenBank sequencing accessions analyzed in
95 this study were AB691782–AB691938, AB693038, AB692786–AB692942, AB693039 (Takenaka and
96 Kawahara 2012), and AB745510-AB745620 (sequenced in this study).

97

98 Results

99 PCR assay for Type AI / Type AII and their geographical distribution

100 All diploid species (*T. boeoticum*, *T. monococcum*, and *T. urartu*) and timopheevii wheat (*T.*
101 *araraticum* and *T. timopheevii*) were Type AII. Type AI was found only in emmer wheat (Table 1). In wild
102 emmer wheat, 82 accessions (44.3%) were Type AI. Type AI wild emmer wheat was distributed across a
103 wide range. In particular, central-eastern wild emmer accessions were all Type AI. On the other hand,
104 Type AII wild emmer accessions were distributed centering on Israel (Fig. 2a). In hulled emmer wheat, 67
105 accessions (62.6%) were Type AII (Table 2). Both Type AI and Type AII were widely distributed in the
106 collection area. However, many accessions of Type AI were spread on the western side centered on
107 Europe, and many accessions of Type AII were spread on the eastern side centered on the Middle East
108 (Fig. 2b). In FT emmer wheat, 188 accessions (92.2%) were Type AI and a few FT emmer accessions of
109 Type AII were distributed centering on Former Yugoslavian countries (Table 2 and Fig. 2c). We could not
110 identify two FT emmer accessions (PI244061 and KU-146) by the PCR assay for Type AI / Type AII
111 because they had a GS-105-type deletion (Fig. 1 and Table 2) (Wilihelm *et al.* 2009).

112

113 The deletion patterns of MITE-like sequences found in Type AII accessions

114 In the PCR assay, a small band was produced from some accessions of Type AII. The small
115 band was caused by a deletion (*ca.* 100 bp) of MITE-like sequences. This deletion was mentioned as Type

116 AIIa in a previous study (Takenaka and Kawahara 2012). In this study, we found that there were two
117 deletion patterns based on sequencing data. Differences in deletion patterns were shown in Fig. 1. One
118 type of deletion was found in most timopheevii wheat, so we named it as araraticum-type-deletion
119 (ara-del). The other type of deletion was found only in wild emmer wheat, so we named it as
120 dicoccoides-type-deletion (dic-del). Dic-del was found in 32 wild emmer accessions in Israel (Fig. 2a,b
121 and Table 3). On the other hand, ara-del was found from most wild timopheevii accessions (100
122 accessions, 97.1%), all domesticated timopheevii accessions, one wild emmer accession (KU-14531), and
123 ten hulled emmer accessions (*T. dicoccon*; PI94633, PI94663, PI254177, PI254189, PI 272533, KU-1533,
124 KU-1538, and KU-3371, *T. ispahanicum*; KU-145 and KU-4580). Only three wild timopheevii accessions
125 (KU-1943, KU-1990, and IG 116177) did not have ara-del and were all found in Turkey.

126

127 Sequence diversity and phylogenetic analysis

128 Genetic relationships among accessions are shown by an NJ tree based on all sequence data (5'
129 UTR , intronic, cording, and 3' UTR regions of *Ppd-A1*, Fig. 3). Accessions were divided into three
130 clades. The first clade was constituted by the A^m genome diploid species (*T. boeoticum* and *T.*
131 *monococcum*), the second one was constituted by the A^u genome diploid species (*T. urartu*), and the third
132 one was constituted by tetraploid wheat (BBAA and GGAA genome species).

133 The A^m genome clade was divided into two groups. One group contained only *T. boeoticum*
134 and another group included both *T. boeoticum* and *T. monococcum* (Fig. 3). The two groups in the A^m
135 genome clade were divided based on some SNPs and three insertion/deletion mutations (14bp, 177bp, and
136 23bp), which were all found in the 5' UTR region of *Ppd-A1* (23bp insertion mutations are shown in Fig.
137 1). In *Ppd-A1* cording and intronic regions, no mutation specific for each group was found.

138 The A^u genome clade was also divided into two groups. The genetic distance between the two

139 groups of the A^u genome clade was smaller than the distance between the two groups of the A^m genome
140 clade (Fig. 3). The two groups were divided based on some SNPs, which were all found in the 5' UTR
141 region of *Ppd-A1*. One 9 bp deletion (CCA repeats), which was specific for one group, was found in the
142 1st exon.

143 The tetraploid wheat clade was divided into two sub-clades. The GGAA genome sub-clade
144 included most GGAA genome accessions and all BBAA genome accessions with ara-del. The BBAA
145 genome sub-clade consisted of most BBAA genome accessions and *T. araraticum* accessions (KU-1943
146 and IG 116177), which do not have ara-del. Wild emmer accessions with dic-del and Type AI emmer
147 accessions formed distinct groups in the BBAA genome sub-clade (Fig. 3).

148 There were 65 SNPs and insertion/deletion variants in *Ppd-A1* coding and intronic regions of
149 tetraploid wheat. Ten polymorphic sites were specific each for timopheevii wheat (excluded accessions
150 without ara-del) or emmer wheat (excluded accessions with ara-del). Emmer wheat that had ara-del was
151 shared in seven polymorphic sites with timopheevii wheat, and timopheevii wheat without ara-del shared
152 these with most emmer wheat (Table 4).

153 Even when the haplotype network based on *Ppd-A1* was constructed, three main clades of
154 *Ppd-A1* were also formed (Fig. 4a). However, in the BBAA sub-clade, the distinction between Type AI
155 and Type AII disappeared. As different from the *Ppd-A1* haplotype network, there were many differences
156 between *Ppd-B1* of emmer wheat and *Ppd-G1* of timopheevii wheat (Fig. 4b). Unlike the phylogenetic
157 tree based on *Ppd-A1*, all hulled emmer wheat with ara-del was included in the *Ppd-B1* group. *T.*
158 *araraticum* accessions without ara-del were also included in the *Ppd-B1* group. On the other hand, one
159 wild emmer accession with ara-del (KU-14531) was included in the *Ppd-G1* group (Fig. 4b).

160

161 Discussion

162 Evolution of emmer wheat based on Type AI and Type AII

163 In wild emmer wheat, both Type AI and Type AII existed but all diploid species were Type AII

164 (Table 1). The phylogenetic tree based on *Ppd-A1* shows that all Type AI accessions are monophyletic

165 (Fig. 3). These results suggest that Type AII is an older type than Type AI and that the Type AI line was

166 derived partially from Type AII lines. Most Type AI wild emmer wheat was found in central-eastern parts

167 of distributions and Type AII wild emmer wheat was found in western parts of distributions centering on

168 Israel (Fig. 2a). This suggests that characteristic mutations of Type AI occurred in central-eastern wild

169 emmer wheat. Luo *et al.* (2007) and Özkan *et al.* (2005 and 2011) showed that wild emmer is divided into

170 central-eastern and western lines and that central-eastern one contributed to domestication. Sixty-seven

171 wild emmer accessions used in this study were typed by Özkan *et al.* (2011) based on ALFP analysis

172 (Table 5 and Table S). Accessions typed as Ib, Ic, and III by Özkan *et al.* (2011) were all Type AI and

173 accessions typed as V were all Type AII with dic-del. Accessions typed as II and IV were both Type AI

174 and Type AII (Table 5). Özkan *et al.* (2011) defined groups I, II and III as central-eastern wild emmer

175 lines and groups IV and V as western wild emmer lines. ALFP analysis detects variations in the whole

176 genome but our study targeted variations that existed in very limited regions. Because of this difference,

177 these results did not correspond completely. However, the differences between Type AI and Type AII may

178 show the differences between central-eastern and western wild emmer. Therefore, we thought that Type

179 AI domesticated hulled emmer was directly domesticated from Type AI wild emmer lines and that Type

180 AII domesticated hulled emmer was not domesticated from Type AII wild emmer lines, but rather arose

181 by introgression between domesticated emmer and Type AII wild emmer around Israel. The introgression

182 between hulled emmer and wild emmer in Israel has already reported (Luo *et al.* 2007). Our previous

183 study dealing with this problem had used only 19 wild emmer accessions (Takenaka and Kawahara 2012),

184 but here we used 185 wild emmer accessions, which further supported the results.

185 More than half of hulled emmer accessions (62.6%) were Type AII (Table 2). This suggested
186 that the introgression between domesticated emmer and Type AII wild emmer occurred at an early stage
187 of evolution and diffusion of hulled emmer wheat. Different from hulled emmer, most accessions of
188 free-threshing (FT) emmer were Type AI (92.2%, Table 2). Type AII FT emmer accessions were rare, but
189 they were distributed in wide areas (Iran, Turkey, Bosnia and Herzegovina, Croatia, Macedonia,
190 Montenegro, Spain, Portugal, and Algeria, Fig. 2c). In Turkey and Iran, there were both Type AII hulled
191 emmer accessions and Type AII FT emmer accessions (Fig. 2b,c). Therefore, Type AII FT emmer may be
192 evolved from Type AII hulled emmer in these regions. On the other hand, we could not find Type AII
193 hulled emmer accessions from other regions where Type AII FT emmer accessions grow. These Type AII
194 FT emmer accessions may have arisen in each region independently or may have been derived from other
195 regions (*e.g.* Turkey and Iran). More research on this unique type of emmer is needed. Whether Type AII
196 FT emmer races were of single origin or multiple origins, the result that almost all FT emmer accessions
197 were Type AI suggested a strong bottleneck effect for domesticated emmer. As the result of this strong
198 bottleneck effect, we could not fully apply the genetic resources of Type AII emmer for wheat cultivated
199 today.
200

201 Evolution of tetraploid wheat based on deletion patterns of MITE-like sequences
202 Type AII accessions with dic-del were found only from wild emmer wheat in Israel (Fig. 2a).
203 This suggested that dic-del was a specific variation for wild emmer in Israel and that wild emmer with
204 dic-del have not influenced domesticated emmer wheat. Therefore, wild emmer accessions with dic-del
205 would contribute greatly as genetic resources of domesticated emmer wheat.
206 Almost all timopheevii wheat having ara-del (Table 3) suggested that this mutation occurred in
207 timopheevii wheat soon after it arrived or in ancestral diploid species, which donated A genomes to

208 timopheevii wheat, and that this mutation was specific for timopheevii wheat. In this study, we found ten
209 hulled emmer accessions with ara-del. This indicated that ara-del, which was found in hulled emmer
210 wheat, was derived from timopheevii wheat. Phylogenetic trees, MJ networks, and SNPs information
211 based on *Ppd-A1* gene regions also supported that the regions of ten hulled emmer wheat accessions
212 originating from timopheevii wheat (Fig. 3, 4a and Table 4). MJ networks based on *Ppd-B1/Ppd-G1*
213 showed that ten hulled emmer wheat accessions with ara-del had not *Ppd-G1* but *Ppd-B1* (Fig. 4b). Their
214 morphological appearances were also accorded with emmer wheat. Moreover, previous studies had
215 treated some hulled emmer accessions with ara-del as emmer wheat and these studies did not report that
216 these accessions had the characteristics of timopheevii wheat (Mori *et al.* 1997; Ishii *et al.* 2001; Asakura
217 *et al.* 2001; Hirosawa *et al.* 2004). Thus, we thought that these ten hulled emmer accessions with ara-del
218 originated from introgression from timopheevii wheat and that chromosome substitution occurred at
219 regions including the *Ppd-A1* gene. *T. araraticum* distributed from the east side of the Fertile Crescent to
220 Transcaucasia, and most hulled emmer accessions with ara-del were found in this region (Iran and
221 Georgia, Fig. 2b). In these regions, populations of *T. araraticum* were colonized as a weed in fields of
222 emmer wheat (Nesbitt and Samuel 1996). Such a situation had chances of interspecific crossing between
223 emmer wheat and weed timopheevii wheat. Because of hybrid sterility, their F_1 usually could not leave F_2
224 generations (Tanaka *et al.* 1979). Hybrid sterility, however, recovered when F_1 hybrids were backcrossed
225 (Maan 1972). In fields of emmer wheat, successive backcrossing with emmer wheat could cause hulled
226 emmer wheat that has part of the timopheevii wheat chromosome. Hulled emmer accessions with ara-del
227 were also found in Europe and North Africa (Hungary, Germany, and Morocco) where timopheevii wheat
228 did not distribute (Fig. 2b). This suggested that hulled emmer wheat, which originated around
229 Transcaucasia, was introduced into Europe and North Africa, via the northern shore of the Black Sea and
230 through the Strait of Gibraltar.

231 One wild emmer accession in Israel (KU-14531) also had ara-del and MJ networks based on
232 *Ppd-B1/Ppd-G1* showed that this accession did not have *Ppd-B1* but *Ppd-G1* (Fig. 4b). This may indicate
233 that the accession was not *T. dicoccoides* but *T. araraticum*. However, *T. araraticum* was not found in
234 Israel where the accession came from, and morphological characteristics showed that the accession was *T.*
235 *dicoccoides*. We need to perform more research on this accession.

236 Three *T. araraticum* accessions (KU-1943, KU-1990 and IG116177) did not have ara-del and a
237 phylogenetic tree based on *Ppd-A1* regions showed that these accessions were included in the BBAA
238 genome sub-clade (Fig. 3). In addition, MJ networks based on *Ppd-B1/Ppd-G1* showed that these
239 accessions were included in the *Ppd-B1* group (Fig. 4b). These results may suggest that these *T.*
240 *araraticum* accessions were not timopheevii wheat but emmer wheat. These accessions had been
241 analyzed as wild timopheevii wheat for RFLP analyses by Mori *et al.* (1995), SSLP by Ishii *et al.* (2001),
242 and chloroplast DNA fingerprinting by Mori *et al.* (2009). These results and the morphological
243 characteristics of these *T. araraticum* accessions showed that the accessions were timopheevii wheat. All
244 *T. araraticum* accessions without MITE-like sequence deletions were found from Southeast Turkey where
245 there were mixed populations of *T. dicoccoides* and *T. araraticum* (Nesbitt and Samuel 1996). In addition,
246 some *T. dicoccoides* lines in Turkey produced hybrids with fertility when crossed with *T. araraticum*
247 (Rawal and Harlan 1975). Thus, we thought that these *T. araraticum* accessions without MITE-like
248 sequence deletions had originated from interspecific crossing with *T. dicoccoides* and that chromosome
249 substitutions occurred at regions including both *Ppd-A1* and *Ppd-G1* genes.

250 Hulled emmer wheat with ara-del and wild timopheevii wheat without MITE-like sequence
251 deletions particularly showed that the gene flow between emmer wheat and timopheevii wheat occurred
252 and that timopheevii wheat, which was of a different lineage to emmer and common wheat, also had
253 important genetic resources for wheat breeding.

354 Fig. 1 Consensus sequences around MITE-like deletions. Gray parts show unique sequences of Type
355 AI/AII and ara-del/dic-del. ① Type AI including 10 wild emmer, 23 hulled emmer, and 90 FT emmer
356 accessions ② Type AI including 4 wild emmer accessions. ③ Type AII including 4 *T. boeoticum*
357 accessions. ④ Type AII including 2 *T. boeoticum* and 3 *T. monococcum* accessions. ⑤ Type AII with
358 dic-del including 4 wild emmer accessions. ⑥ Type AII with ara-del including 1 wild emmer, 10 hulled
359 emmer, and 13 timopheevii accessions. ⑦ Type AII without MITE-like sequence deletions including 37 *T.*
360 *urartu*, 8 wild emmer, 21 hulled emmer, 4 FT emmer, and 2 wild timopheevii accessions. ⑧ GS-105
361 deletion including 2 FT emmer accessions.

362

363 Fig. 2 Geographical distribution of Type AI and Type AII emmer accessions. Only the ratio of each type
364 is shown. (a) Distribution of wild emmer accessions shown by collected regions. (b) Distribution of
365 hulled emmer accessions shown by collected countries. (c) Distribution of FT emmer accessions shown
366 by collected countries.

367

368 Fig. 3 Neighbor-joining phylogenetic tree built with the 5' UTR, intronic, coding, and 3' UTR regions
369 of *Ppd-A1*. Bootstrap values (1,000 replicates, more than 80) are shown next to the branches. Analyses
370 include 233 accessions. Type AI emmer, partial Type AII emmer, Type AII emmer with dic-del and
371 diploid accessions are compressed.

372

373 Fig. 4 MJ networks derived from DNA sequence haplotypes among accessions. (a) Haplotypes of
374 *Ppd-A1*. (b) Haplotypes of *Ppd-B1* and *Ppd-G1*. Black part, gray part, hatched part on white background,
375 and hatched part on gray background show emmer wheat, timopheevii wheat, the A^u genome species (*T.*
376 *urartu*), and A^m genome species (*T. boeoticum* and *T. monococcum*). A small white circle means a
377 substitution and many substitutions are shown by figures.

Table 1 The number of accessions divided by collected countries, excluding domesticated emmer.
