1 Introduction

This article is a short review of probabilistic representation of quantum particle system interacting with a quantum field considered in [6]. To analyze quantum physics model mathematically, the state space $\mathcal{H}$ of the system is given by a Hilbert space. In many cases, the total Hamiltonian $H$ of the system is a self-adjoint operator on $\mathcal{H}$. Here assume that $H$ is self-adjoint and bounded from below. Functional integral representation of $H$ is a probabilistic representation of the strongly continuous semi-group $\{e^{-tH}\}_{t\geq 0}$ generated by $H$. It is seen that the spectral analysis of $H$ can be stochastically investigated by using functional integral representations. For the details of functional integral representation and its application of quantum physics model, refer to [5].

We investigate the system of a semi-relativistic particle interacting with a Klein-Gordon field. Here we assume that the particle obey the relativistic Schrödinger operator and the ultraviolet cutoff condition is imposed on the Klein-Gordon field. The functional representation of relativistic Schrödinger operator is investigated in [2]. The particle in the electromagnetic potential with spin is considered in [3] and the spatial decay of the bound states is estimated in [4]. In the following section, the functional integral representation of the relativistic Schrodinger operator is derived by Levy subordinator according to [3]. In constructive quantum field theory, Klein-Gordon field is constructed by the methods of stochastic process, and the functional integral representation is derived by using Euclidean field. By using the functional integral representations of relativistic Schrödinger operator and Klein-Gordon field, the functional integral representation of the interacting system between semi-relativistic particle and the Klein-Gordon field is derived. From the obtained functional integral representation, we see that if the ground states exist, it is unique and its decay rate can be estimated.
2 Relativistic Schrödinger Operator and Klein-Gordon Field

We assume that the particle’s Hamiltonian is given the relativistic Schrödinger operator with potential $H_p = \sqrt{-\Delta + M^2} - M + V$ on the Hilbert space $L^2(\mathbb{R}_x^d)$. Here $M > 0$ is the rest mass of the particle. Let us set $h_{rel}(s) = \sqrt{s + M^2} - M$, $s > 0$. Since $h_{rel}$ is a Bernstein function, it is seen that there exists a Lévy subordinator $\{T_t\}_{t \geq 0}$ on a probability space $(\Omega_{rel}, \mathcal{B}_{rel}, P_{rel})$ satisfying $\mathbb{E}_{rel}[e^{-sT_t}] = e^{-th_{rel}(s)}$ where $\mathbb{E}_{rel}[X] = \int_{\Omega_{rel}} X(\eta)dP_{rel}(\eta)$. Let $\{B_t\}_{t \geq 0}$ be $d$-dimensional Brownian motion starting $x$ on the probability space $(\Omega_{BM}, \mathcal{B}_{BM}, P_{BM}^x)$. We introduce the probability space $(\Omega_p, \mathcal{B}_p, P_p^x) = (\Omega_{rel} \times \Omega_{BM}, \mathcal{B}_{rel} \otimes \mathcal{B}_{BM}, P_{rel} \otimes P_{BM}^x)$. Then the following functional integral representation for the semi-relativistic particles holds. (See [3]; Theorem 3.8):

$$e^{-tH_p}\psi(x) = \mathbb{E}_p^x[\psi(X_t)e^{-\int_0^t V(X_s)ds}],$$

where $X_t((\eta, \omega)) = B_{T_t}(\eta)(\omega)$ and $\mathbb{E}_p^x[Z] = \int_{\Omega_p} Z(\xi)dP_p^x(\xi)$.

Klein-Gordon field is constructed as follows. The Hilbert space $\mathcal{K}_{KG}$ is defined by the completion of the pre-Hilbert space which consists of real valued tempered distribution $f \in S'_\text{real}(\mathbb{R}^d)$ satisfying $\|\omega^{-1/2}f\|_{L^2} < \infty$. Here the inner product is given by $(g, f)_{\mathcal{K}_{KG}} = (\omega^{-1/2}g, \omega^{-1/2}f)_{L^2}$. Then from a general theorem on Gaussian random process indexed by Hilbert spaces, there exist a probability space $(\mathcal{Q}_{KG}, \mathcal{B}_{KG}, P_{KG})$ and a random process $\{\phi_{f}\}_{f \in \mathcal{K}_{KG}}$ which satisfies $\mathbb{E}[e^{-it\phi_f}] = \exp(-\|f\|^2_{\mathcal{K}_{KG}} t^2/4)$. Let $H_{KG} = d\Gamma(\omega)$ be the second quantization of $\omega$. Then Klein-Gordon field is defined by the triplet $(L^2(\mathcal{Q}_{KG}), H_{KG}, \{\phi_{f}\}_{f \in \mathcal{K}_{KG}})$. Let $\mathcal{K}_E$ be the completion of the pre-Hilbert space which consists of real-valued tempered distribution $u \in S'_\text{real}(\mathbb{R}^{1+d})$ satisfying $\|\omega^{-1}u\|_{L^2} < \infty$. Here the inner product is given by $(v, u)_{\mathcal{K}_E} = (\omega^{-1}v, \omega^{-1}u)_{L^2}$. Then similar to the construction of the Klein-Gordon field, it is seen that there exist a probability space $(\mathcal{Q}_E, \mathcal{B}_E, P_E)$ and a Gaussian random process $\{\phi_{E}^{u}\}_{u \in \mathcal{K}_E}$ satisfying $\mathbb{E}[e^{-it\phi_{E}^{u}}] = \exp(-\|u\|^2_{\mathcal{K}_E} t^2/4)$. Then the next functional integral representation follows: (Refer to e.g. [1]; Theorem 7.19).

$$(\Phi, e^{-t(H_b + P(\phi(f))))\Psi}_{L^2(\mathcal{Q}_{KG})} = \mathbb{E}_E[(\Phi)(J_t\Psi)e^{-\int_0^t P(\phi_{E}^{\phi_{E}^{u}})ds}],$$

where $J_t$ is an isometric operator from $L^2(\mathcal{Q}_{KG})$ to $L^2(\mathcal{Q}_E)$ and $P = \sum_{j=1}^{2n} c_j \lambda_j$. 

3 Main Theorem

The interaction system between the semi-relativistic particle and a scalar Bose fields is defined as follows. The state space for the system is given by $\mathcal{H} = L^2(\mathbb{R}^d_x) \otimes L^2(Q_0)$. The total Hamiltonian of the system is defined by form sum of the free Hamiltonian and interaction

$$H_\kappa = H_0 + \kappa H_1, \quad \kappa \in \mathbb{R},$$

where $H_0 = H_0 \otimes I + I \otimes H_{KG}$ and $H_1 = P(\phi_{\rho_{\Lambda,x}})$ with $P(\lambda) = \sum_{j=1}^{2n} c_j \lambda^j, c_j \in \mathbb{R}$, $j = 1, \ldots, 2n-1$, $c_{2n} > 0$ and $\rho_{\Lambda,x}$ satisfies that $\hat{\rho}_{\Lambda,x}(k) = \hat{\rho}_\Lambda(k)e^{ikx}$ with the characteristic function $\rho_\Lambda$ on $\mathbb{R}^d$.

By applying Feynman-Kac formula of relativistic Shr"odinger operator and Klein-Gordon and Trotter-Kato product formula, the functional integral representation of $H_\kappa$ is derived.

Theorem 1
Assume that $V$ is relativistic Kato-class. Then it follows that

$$\langle \Phi, e^{-tH_\kappa}\Psi \rangle_{\mathcal{H}} = \int_{\mathbb{R}^d} \mathbb{E}_{p \otimes E}^{x}[(J_0\Phi(X_0))(J_t\Psi(X_t))e^{-\int_0^t V(X_s)ds}e^{-\kappa P(\phi^E(\int_0^t \delta_s \otimes \rho_{X_s}ds))}]dx.$$

It is seen that $e^{-tH_0}$ and $e^{-tH_{KG}}$ are positivity improving operators. In addition, the exponential decay of the bound states with respect to spacial variable is proven in [4]. Then from the functional integral representation of $H$, the next corollary immediately follows.

Corollary 2
Assume that $V$ is relativistic Kato class and $H_\kappa$ has the ground state. Then, following (1) and (2) holds.
(1) The ground state is unique.
(2) If $V(x) \to 0$ or $\infty$ as $|x| \to \infty$, the bound state has exponential decay with respect to spatial variable.
