ABSTRACT
Aims/Introduction: Endoplasmic reticulum (ER) stress is one of the contributing factors in the development of type 2 diabetes. To investigate the cytoprotective effect of glucagon-like peptide 1 receptor (GLP-1R) signaling in vivo, we examined the action of exendin-4 (Ex-4), a potent GLP-1R agonist, on β-cell apoptosis in Akita mice, an animal model of ER stress-mediated diabetes.

Materials and Methods: Ex-4, phosphate-buffered saline (PBS) or phlorizin were injected intraperitoneally twice a day from 3 to 5 weeks-of-age. We evaluated the changes in blood glucose levels, bodyweights, and pancreatic insulin-positive area and number of islets. The effect of Ex-4 on the numbers of C/EBP-homologous protein (CHOP)-, TdT-mediated dUTP-biotin nick-end labeling (TUNEL)- or proliferating cell nuclear antigen-positive β-cells were also evaluated.

Results: Ex-4 significantly reduced blood glucose levels and increased both the insulin-positive area and the number of islets compared with PBS-treated mice. In contrast, there was no significant difference in the insulin-positive area between PBS-treated mice and phlorizin-treated mice, in which blood glucose levels were controlled similarly to those in Ex-4-treated mice. Furthermore, treatment of Akita mice with Ex-4 resulted in a significant decrease in the number of CHOP-positive β-cells and TUNEL-positive β-cells, and in CHOP mRNA levels in β-cells, but there was no significant difference between the PBS-treated group and the phlorizin-treated group. Proliferating cell nuclear antigen staining showed no significant difference among the three groups in proliferation of β-cells.

Conclusions: These data suggest that Ex-4 treatment can attenuate ER stress-mediated β-cell damage, mainly through a reduction of apoptotic cell death that is independent of lowered blood glucose levels. (J Diabetes Invest, doi: 10.1111/j.2040-1124.2010.00075.x, 2011)

INTRODUCTION
Type 2 diabetes is a chronic metabolic disorder characterized by the loss of β-cell function and mass. The mechanisms underlying the loss of β-cell function and mass are not fully understood, but recent studies have shown that endoplasmic reticulum (ER) stress is one of the causes of β-cell damage in diabetes⁴. Owing to increased demand for insulin secretion, β-cells show a highly developed ER. The ER has a number of important functions, such as post-translational modification, folding and assembly of newly synthesized secretory proteins⁵–⁷. Thus, the ER plays an essential role in cell survival. ER function can be impaired by various conditions, including inhibition of protein glycosylation, reduction in formation of disulfide bonds, calcium depletion from the ER lumen, impairment of protein transport from the ER to the Golgi and expression of malfolded proteins⁵. Various physiological or pathological conditions that compromise ER functions are collectively termed ER stress⁴. To alleviate ER stress and promote cell survival, an adaptive response, known as unfolded protein response (UPR) is activated. UPR comprises translational attenuation, induction of chaperones and ER stress-associated degradation (ERAD). However, prolonged activation of UPR can ultimately lead to cell death by apoptosis.

Increased demand for insulin secretion under certain conditions, such as chronic hyperglycemia, might result in β-cell overload. Chronic hyperglycemia in diabetes can therefore induce persistent ER stress, cause β-cell dysfunction and finally lead to a reduction in β-cell mass through apoptosis⁵.

Glucagon-like peptide 1 (GLP-1) is a physiological incretin, an intestinal hormone released in response to nutrient
GLP-1’s effect on β-cell in Akita mice

In the present study, we investigated the cytoprotective effect of GLP-1R signaling in vivo on ER stress-mediated apoptotic cell death by using Akita mice, an animal model of ER stress-mediated diabetes mellitus. Akita mice have a point mutation in the insulin 2 gene, resulting in misfolding of insulin that leads to severe ER stress17,18. To exclude the possibility that the effect of Ex-4 on β-cells is mediated through improved blood glucose levels, we used three groups of mice: Akita mice treated with phosphate-buffered saline (PBS), Ex-4, or the sodium-coupled glucose transporter inhibitor phlorizin, which decreases blood glucose levels without increasing insulin secretion.

MATERIALS AND METHODS

Experimental Animals
Male C57BL/6 mice and male Akita mice were obtained from Shimizu (Kyoto, Japan). The animals were housed under a light/dark cycle of 12 h with free access to food and water. All experiments were approved by the Kyoto University Animal Care Committee.

In vivo Treatment
The mice were given twice daily intraperitoneal injections of PBS, Ex-4 (24 nmol/kg) or phlorizin (0.3 g/kg) for 2 weeks (from 3 to 5 weeks-of-age). Blood glucose levels were measured every third day by enzyme electrode method using a portable glucose analyzer (Glutest sensor; Sanwakagaku, Nagoya, Japan). Blood samples were collected from tail cuttings from these mice fed ad libitum. At the end of the experimental period, blood samples were collected from the inferior vena cava under anesthesia to determine the plasma glycoalbumin levels (Oriental Yeast, Tokyo, Japan). Pancreas samples from each of the animal groups were obtained for histological evaluation, and islets were isolated for measurement of insulin content and RNA extraction.

Evaluation of Pancreatic Insulin-Positive Area and Number of Islets
The pancreas samples were fixed in Bouin’s solution. Serial 5-μm paraffin-embedded tissue sections were mounted on slides. After rehydration, sections were incubated with polyclonal rabbit anti-insulin antibodies (Santa Cruz Biotechnology, Santa Cruz, CA, USA), with a biotinylated goat anti-rabbit antibody (DAKO, Carpinteria, CA, USA), and then with a streptavidin peroxidase conjugate and substrate kit (DAKO) using standard protocols. The total pancreas area and insulin-positive area were quantified on five distal, random, non-overlapping sections from five mice of each group using a BZ-8100 microscope equipped with a BZ-Analyzer (Keyence, Osaka, Japan). Insulin-positive areas and the number of islets of each group were adjusted by total pancreas area15.

Measurement of Insulin Contents of Isolated Islets
Pancreatic islets were isolated by collagenase digestion. To determine insulin contents, islets were homogenized in 400 μL acid ethanol (37% HCl in 75% ethanol, 15:1000 [v/v]) and extracted at 4°C overnight. The acidic extracts were dried by vacuum, reconstituted and subjected to insulin measurement. The amount of immunoreactive insulin was determined by radioimmunoassay (RIA).

Measurement of mRNA Expression of C/EBP-Homologous Protein and BiP in Isolated Islets
Measurement of mRNA expression of C/EBP-homologous protein (CHOP) and BiP was carried out by quantitative reverse transcription polymerase chain reaction (RT–PCR) as described previously19. Briefly, total RNA was extracted from isolated islets with an RNaseq mini kit (Qiagen, Valencia, CA, USA) and treated with DNase (Qiagen). cDNA was prepared by SuperScript Reverse Transcriptase system (Invitrogen, Carlsbad, CA, USA) according to the manufacturer’s instructions. CHOP mRNA levels and BiP mRNA levels in the islets were measured by quantitative RT–PCR using an ABI PRISM 7000 Sequence Detection System (Applied Biosystems, Foster City, CA, USA). The sequences of forward and reverse primers to evaluate

**P < 0.05, **P < 0.01 vs PBS-treated Akita mice.
CHOP expression were 5'-GAGCT- GGAAGCCTGGTATGA-3' and 5'-GGACGCAGGGTCAAGTAG-3', respectively; the sequences of forward and reverse primers to evaluate BiP expression were 5'-TTTCTGCCATGGTTCACTAA-3' and 5'-GCTGGGCATCATTGAAGTAAG-3', respectively; and the sequences of forward and reverse primers to evaluate glyceraldehyde 3-phosphate dehydrogenase (GAPDH) expression were 5'-AGCTCACTGGCATGGCTTCCG-3' and 5'-GCCTGCTTCACCACCTTCTTGATG-3', respectively. SYBER Green PCR Master Mix (Applied Biosystems) was prepared for the PCR run. Thermal cycling conditions were denatured at 95°C for 10 min followed by 50 cycles at 95°C for 15 s and 60°C for 1 min. Total CHOP and total BiP levels were corrected by GAPDH mRNA levels.

**Immunofluorescence Staining**

For pancreatic CHOP and insulin immunohistochemistry, the tissues were fixed and embedded in paraffin. Serial 5-µm sections were stained with anti-CHOP/GADD153 (Santa Cruz Biotechnology) and anti-insulin (DAKO) antibodies using standard protocols. Insulin immunopositive areas were measured on five distal, random, non-overlapping sections from five mice of each group using a BZ-8100 fluorescence microscope equipped with a BZ-Analyzer (Keyence), and the number of cells showing

![Figure 2](image-url)
both nuclear CHOP and cytoplasmic insulin immunopositivity was determined. The ratio of CHOP-positive β-cells was calculated by adjusting the number of CHOP-positive β-cells by the insulin-positive area. The effect of Ex-4 treatment on β-cell replication and apoptosis was evaluated histologically by proliferating cell nuclear antigen (PCNA) staining (Abcam, Cambridge, MA, USA) and TdT-mediated dUTP-biotin nick-end labeling (TUNEL) staining (Takara Bio, Otsu, Japan), respectively. The ratio of TUNEL-positive and PCNA-positive β-cells was also calculated as described earlier.

**Statistical Analysis**
Data are presented as means ± SEM. Statistical analyses were carried out by unpaired t-test. A P-value of <0.05 was considered significant.

**RESULTS**

**Effect of Ex-4 on Hyperglycemia and Bodyweight in Akita Mice**
Akita mice showed acute and progressive hyperglycemia at 14 days after birth and thereafter. Twice-daily intraperitoneal injection of Ex-4 from 3 to 5 weeks-of-age significantly reduced blood glucose levels compared with those in PBS-treated mice (Figure 1a). Plasma glucose levels in phlorizin-treated Akita mice were similar to those in Ex-4-treated mice. Plasma glycoalbumin levels were significantly lower in the Ex-4- and phlorizin-treated groups than those in the PBS-treated group, but no significant difference was observed between the Ex-4- and phlorizin-treated groups (12.9 ± 1.5 vs. 8.7 ± 0.7 vs. 8.2 ± 0.6, respectively, n = 10–12). Ex-4 treatment or phlorizin treatment did not change bodyweight compared with PBS treatment (Figure 1b). Ex-4 or phlorizin treatment did not change the amount of food intake assessed at 4 weeks-of-age (data not shown).

**Effect of Ex-4 on Insulin-Positive Area and Number of Islets**
Preservation of β-cell morphology was observed by treatment with Ex-4, as shown in Figure 2a. Quantitative histological analyses showed that Ex-4 treatment significantly increased both the insulin-positive area and the number of islets, whereas there was no significant difference between the PBS-treated group and the phlorizin-treated group (Figure 2b,c).

**Effect of Ex-4 on Pancreatic Insulin Content**
Figure 2d shows the effect of Ex-4 treatment on insulin content in pancreatic islets. Treatment with Ex-4 significantly increased insulin content in isolated islets, but phlorizin treatment did not.

**Quantitative Estimation of CHOP and BiP Expression Levels by Real-Time PCR**
The expression levels of CHOP mRNA are shown in Figure 3a, and those of BiP mRNA are shown in Figure 3b. Ex-4 significantly lowered the expression levels of CHOP and BiP mRNA, but there was no significant difference in the expression levels of CHOP or BiP mRNA between the phlorizin- or PBS-treated groups.

**Effect of Ex-4 on the Ratio of CHOP- and BiP mRNA in Akita Mice**

**DISCUSSION**
Akita mice are widely used as an animal model of ER stress-mediated diabetes. Akita mice have a point mutation (C96T) in the insulin 2 gene that disrupts the disulfide bond formation between the A and B chains of proinsulin, resulting in a drastic conformational change of the molecule. The unfolded proinsulin accumulates to the ER, causing severe ER stress leading to β-cell apoptosis. In humans, it has recently been shown that a mutation in the insulin gene, which is identical...
to that in the Akita mouse, causes permanent neonatal diabetes within the first month of life that requires lifelong insulin injection. In the present study, we have shown that Ex-4 treatment has a protective effect on β-cells in Akita mice. The insulin-positive area and the number of islets were maintained along with a decreased ratio of CHOP- and TUNEL-positive cells in the islets, showing that the major effect of Ex-4 treatment in the maintenance of β-cell mass is through decreasing β-cell apoptosis in response to ER stress. Because phlorizin decreases blood glucose levels without increasing insulin secretion, it might well reduce ER stress by decreasing the insulin demand. However, in contrast to the Ex-4 treatment, phlorizin treatment failed to show a reduction of ER stress or β-cell protective effects against insulin resistance.

Figure 4 | Ex-4 treatment decreased the ratio of C/EBP-homologous protein (CHOP)-positive β-cells in Akita mice. (a) Representative mouse pancreata at 5 weeks-of-age stained with insulin (red), CHOP (green) and DAPI (blue). (b) The number of CHOP-positive β-cells normalized per insulin-positive area was quantified as described in Materials and Methods. Each column represents mean ± SE. **P < 0.01.

Figure 5 | Ex-4 treatment decreased the ratio of TUNEL-positive β-cells. (a) Representative mouse pancreata at 5 weeks-of-age stained with insulin (red) and TUNEL (green). apoptosis in our conditions. These findings show that Ex-4 has a direct effect on ER stress-mediated β-cell apoptosis that is independent of decreased insulin demand.

There are several in vitro and in vivo studies showing that GLP-1R agonists inhibit β-cell apoptosis, and several molecular mechanisms have been suggested. For example, GLP-1 treatment decreases the expression levels of proapoptotic protein caspase-3 and increases those of anti-apoptotic protein bcl-2 in isolated human islets. It also has been shown that the anti-apoptotic effect of Ex-4 is associated with the activation of protein kinase B/Akt through PKA-dependent phosphorylation of CREB. There are some reports that GLP-1 ameliorates ER stress. Yusta et al. found that treatment by Ex-4 reduces blood glucose levels in obese db/db mice along with a decrease in the number of CHOP-positive β-cells. Tsunekawa et al. reported a beneficial effect of Ex-4 on β-cell damage in calmodulin-overexpressing transgenic (CaMTg) mice that develop diabetes through ER stress-mediated β-cell apoptosis. They found that Ex-4 treatment reduced blood glucose levels while retaining the insulin-positive areas and decreasing the expression levels of CHOP mRNA in CaMTg mice. In vitro studies have found that rapid recovery from translational attenuation or upregulation of BiP and JunB accounts for the attenuation of ER stress-mediated β-cell apoptosis. Therefore, the possibility remains that reduced hyperglycemia attenuates persistent ER stress and ameliorates β-cell apoptosis. Our present findings clearly show that Ex-4 treatment attenuates ER stress-mediated β-cell damage in Akita mice through a reduction of apoptotic cell death that is independent of decreased blood glucose levels.

Although several studies have found that the cytoprotective effect of GLP-1R signaling is not only through inhibition of β-cell apoptosis, but also through stimulation of β-cell proliferation, we did not find any effect of Ex-4 treatment on β-cell proliferation. It is possible that the administration period in the present study was too short to observe β-cell proliferation by Ex-4 or that stimulation of β-cell proliferation does not play a significant role in the cytoprotective effect of GLP-1R signaling in Akita mice. The ratio of PCNA-positive β-cells was increased not only in the Ex-4-treated group of Akita mice, but also in the phlorizin-treated group and the untreated group compared with that in wild-type C57BL/6 mice. Whether or not this result can be attributed to the phenotype of Akita mice requires further study.

Islet mass is reported to be decreased in patients with type 2 diabetes at the time of diagnosis. Although Ex-4 is in clinical use for treatment of type 2 diabetes, superiority of Ex-4 over the other antidiabetic drugs has not been shown. Our data confirm the previous findings of a beneficial effect of Ex-4 on glycemic control, but also suggest that Ex-4 has a direct β-cell-protective effect independently of improved glycemic control. Thus, Ex-4 and other GLP-1R agonists might well be more effective than other antidiabetic drugs in clinical use in terms of alleviating β-cell damage and maintaining β-cell mass for diabetic patients.

Figure 6 | Ex-4 treatment did not significantly increase the ratio of PCNA-positive β-cells. (a) Representative mouse pancreata at 5 weeks-of-age stained with insulin (red) and PCNA (green). (b) The number of PCNA-positive β-cells normalized per insulin-positive area was quantified as described in Materials and Methods. Each column represents mean ± SE.
