22 diaminopropionyl]-L-Ala-L-Arg-NH<sub>2</sub>

1 Neutral salts activate and stabilize thermolysin. In this study, to explore the  
2 mechanism, we analyzed the interaction of 8-anilinonaphthalene 1-sulphonate (ANS)  
3 and thermolysin by ANS fluorescence. At pH 7.5, the fluorescence of ANS increased  
4 and blue-shifted with increasing concentrations (0–2.0  $\mu\text{M}$ ) of thermolysin, indicating  
5 that the anilinonaphthalene group of ANS binds with thermolysin through hydrophobic  
6 interaction. ANS did not alter thermolysin activity. The dissociation constants ( $K_d$ ) of  
7 ANS and thermolysin was  $33 \pm 2 \mu\text{M}$  at 0 M NaCl at pH 7.5, decreased with increasing  
8 NaCl concentrations, and reached  $9 \pm 3 \mu\text{M}$  at 4 M NaCl. The  $K_d$  values were not varied  
9 ( $31\text{--}34 \mu\text{M}$ ) in a pH range of 5.5–8.5. This suggests that at high NaCl concentrations,  
10  $\text{Na}^+$  and/or  $\text{Cl}^-$  ions bind with thermolysin and affect the binding of ANS with  
11 thermolysin. Our results also suggest that the activation and stabilization of thermolysin  
12 by NaCl are partially brought about by the binding of  $\text{Na}^+$  and/or  $\text{Cl}^-$  ions with  
13 thermolysin.

17

1 Thermolysin [EC 3.4.24.27] is a thermostable neutral metalloproteinase produced  
2 in the culture broth of *Bacillus thermoproteolyticus*.<sup>1,2)</sup> It consists of 316 amino acid  
3 residues with one zinc ion required for enzyme activity and four calcium ions required  
4 for structural stability.<sup>3-6)</sup> X-ray crystallographic analysis has revealed that it consists of  
5 a  $\beta$ -rich N-terminal domain and an  $\alpha$ -helical C-terminal domain.<sup>7,8)</sup> It catalyzes  
6 specifically the hydrolysis of peptide bonds containing hydrophobic amino acid  
7 residues.<sup>8,9)</sup> Thermolysin is widely used for peptide bond formation through reverse  
8 reaction of hydrolysis.<sup>2)</sup>

9 Thermolysin activity increases with increasing concentrations of neutral salts in an  
10 exponential fashion.<sup>10-16)</sup> The ratios of the specificity constant ( $k_{\text{cat}}/K_m$ ) at 4 M NaCl to  
11 that at 0 M NaCl of thermolysin were 13–15 in the hydrolysis of neutral substrate *N*-[3-  
12 (2-furyl)acryloyl]-glycyl-L-leucine amide (FAGLA) and 6–7 in the hydrolysis of  
13 negatively charged substrate *N*-carbobenzoxy-L-aspartyl-L-phenylalanine methyl ester  
14 (ZDFM) at pH 7.0 at 25°C.<sup>10-16)</sup> Thermolysin stability increases with increasing NaCl  
15 concentration [NaCl] from zero to 1 M and then decreases with [NaCl] up to 4 M: the  
16 first-order rate constant,  $k_{\text{obs}}$ , of the thermal inactivation at 70°C, at pH 7.5, at 0, 1, and  
17 4 M NaCl were 3.4, 1.2, and  $2.8 \times 10^{-4} \text{ s}^{-1}$ , respectively.<sup>12, 16)</sup> The ratio of the first-order  
18 rate constant ( $k_{\text{obs}}$ ) of thermal inactivation at 70°C at 0 M NaCl to that at 1 M NaCl of  
19 thermolysin was 3.<sup>12)</sup> To explore the mechanism of salt-induced activation and  
20 stabilization of thermolysin, we made a preliminary X-ray crystallographic analysis of  
21 thermolysin in the presence of 4 M NaCl.<sup>17)</sup> Two conformers in the active site were  
22 detected in the absence of NaCl, whereas only one was observed in the presence of 4 M  
23 NaCl. However, little is known about the mechanism.<sup>17)</sup>

24 Several mutations that affect thermolysin activity and/or stability have been  
25 identified.<sup>16,18-21)</sup> Of such mutations, Asp150→Glu markedly decreased the NaCl-  
26 induced activation and stabilization while Asn116→Asp did not exhibit any such  
27 marked decrease.<sup>16)</sup> This suggests that the binding of  $\text{Na}^+$  and/or  $\text{Cl}^-$  with certain  
28 residues of thermolysin is involved in the NaCl-induced activation and stabilization.<sup>16)</sup>

1 8-Anilinonaphthalene 1-sulphonate (ANS) is a fluorescent probe.<sup>22)</sup> It has  
2 hydrophobic and hydrophilic groups. It emits a large fluorescence energy when the  
3 anilinonaphthalene group binds with proteins through hydrophobic interaction, while it  
4 does not emit fluorescence when the sulphonic group binds with proteins through  
5 electrostatic interaction.<sup>23)</sup> ANS is widely used for the analysis of proteins.<sup>24–28)</sup> We  
6 previously reported the interaction of ANS and human matrix metalloproteinase 7  
7 (MMP-7).<sup>29)</sup>

8 In the present study, to explore the mechanism of salt-induced activation and  
9 stabilization of thermolysin, we analyzed the interaction of ANS and thermolysin. The  
10 results indicate that ANS binds with thermolysin through hydrophobic interaction and  
11 that the binding is affected by NaCl.

## 12 13 **Materials and Methods**

14  
15 *Materials.* ANS (Lot CM10-118, 299.34 Da) was purchased from AnaSpec Inc.  
16 (San Jose, CA). The concentration of ANS was determined spectrophotometrically  
17 using the molar absorption coefficient at 350 nm,  $\epsilon_{350}$ , of  $5,000 \text{ M}^{-1} \text{ cm}^{-1}$ .<sup>10,11)</sup> A three-  
18 times-crystallized and lyophilized preparation of thermolysin (Lot TIDC391, 34.6 kDa)  
19 was purchased from Daiwa Kasei (Osaka, Japan). The preparation was used without  
20 further purification. The thermolysin solution was filtered through a Millipore  
21 membrane filter, Type HA (pore size, 0.45  $\mu\text{m}$ ), before use. The concentration of  
22 thermolysin was determined using  $\epsilon_{277}$  of  $63,000 \text{ M}^{-1} \text{ cm}^{-1}$ .<sup>10,11)</sup> FAGLA (Lot 111K1764)  
23 was purchased from Sigma (St. Louis, MO). The concentration of FAGLA was  
24 determined using  $\epsilon_{345}$  of  $766 \text{ M}^{-1} \text{ cm}^{-1}$ .<sup>10,11)</sup> MOCac-PLGL(Dpa)AR (1,093.2 Da)<sup>30)</sup> and  
25 (MOCac-PLG) (501.54 Da) were purchased from Peptide Institute (Osaka, Japan).  
26 Their concentrations were determined by the denoted molecular weights. All other  
27 chemicals were from Nacalai Tesque (Kyoto, Japan).

28

1           *Fluorometric analysis of ANS.* Pre-incubation (1,000  $\mu$ l) was initiated by mixing  
2 10  $\mu$ l of the ANS solution (2,500  $\mu$ M in 40 mM HEPES buffer at pH 7.5, 10 mM CaCl<sub>2</sub>  
3 (buffer A), 0–4.0 M NaCl, 0–490  $\mu$ l of buffer A, and 0–500  $\mu$ l of the thermolysin  
4 solution (4.0  $\mu$ M in buffer A) at 25°C for 10 min. After the pre-incubation, the  
5 fluorescence spectra were measured with excitation at 380 nm and emission at 400-600  
6 nm with a Shimadzu RF-5300PC fluorescence spectrophotometer at 25°C.

7  
8           *HPLC analysis of the thermolysin-catalyzed hydrolysis of MOCac-PLGL(Dpa)AR.*

9 MOCac-PLGL(Dpa)AR-hydrolyzing activity was determined by methods described  
10 previously.<sup>31,32</sup> Briefly, pre-incubation (240  $\mu$ l) was initiated by mixing 0–50  $\mu$ l of the  
11 ANS solution (2,500  $\mu$ M in buffer A), 0–236  $\mu$ l of buffer A, and 4  $\mu$ l of the thermolysin  
12 solution (2.0  $\mu$ M in buffer A) at 25°C for 10 min. The reaction was initiated by adding  
13 10  $\mu$ l of the substrate solution (0.5 mM) dissolved in DMSO to 240  $\mu$ l of the pre-  
14 incubated solution (total volume 250  $\mu$ l) at 25°C. The initial concentrations of  
15 thermolysin, substrate, ANS, and DMSO were 32 nM, 20  $\mu$ M, 0–500  $\mu$ M, and 4% v/v,  
16 respectively. The reaction was stopped at appropriate times, by mixing 100  $\mu$ l of the  
17 reaction solution with 400  $\mu$ l of 1% trifluoroacetic acid (TFA). This mixture (100  $\mu$ l)  
18 was then applied to reversed-phase HPLC done on a TSKgel ODS-80Ts column (4.6  
19 mm inner diameter x 150 mm) (Tosoh, Tokyo) equilibrated with 0.1% TFA, 20% v/v  
20 acetonitrile. A linear gradient was generated from 20 to 70% acetonitrile at a retention  
21 time of 5 min over 20 min at a flow-rate of 1.0 ml/min. The absorption of elutes was  
22 detected at 335 nm. The substrate and its two products, MOCac-PLG and L(Dpa)AR,  
23 were separated, and they were evaluated by the respective peak areas. Reaction rate was  
24 determined from the time course of the production of MOCac-PLG.

25  
26           *Thermal inactivation of thermolysin.* Thermal inactivation of thermolysin was  
27 examined by methods described previously.<sup>16</sup> Briefly, 100  $\mu$ L of a solution containing

1 1.0  $\mu\text{M}$  thermolysin, in 50 mM acetate-NaOH buffer at pH 3.5, 4.0, and 4.5, 50 mM  
2 MES-NaOH buffer at pH 5.0, 5.5 and 6.5, 50 mM HEPES-NaOH buffer at pH 7.5 and  
3 8.0 and 50 mM AMPSO-NaOH buffer at pH 8.5 and 9.0, each containing 10 mM  $\text{CaCl}_2$   
4 was incubated at 70°C for specified durations (30, 60, 90, 120, 150, or 180 min). Then it  
5 was incubated at 25°C for 5 min. Relative activity for FAGLA hydrolysis was  
6 determined as described above. Under the assumption that the thermal inactivation is  
7 irreversible and consists of only one step, the first-order rate constant ( $k_{\text{obs}}$ ) of the  
8 inactivation was evaluated by plotting the logarithm of the activity ( $k_{\text{cat}}/K_{\text{m}}$ ) against the  
9 duration of thermal treatment.

#### 11 *Spectrophotometric analysis of the thermolysin-catalyzed hydrolysis of FAGLA.*

12 FAGLA-hydrolyzing activity was determined by methods described previously.<sup>10,11)</sup>  
13 Briefly, the reaction was initiated by adding 50  $\mu\text{l}$  of the thermolysin solution to 950  $\mu\text{l}$   
14 of the substrate solution in buffer at various pH above described (total volume 1,000  $\mu\text{l}$ )  
15 at 25°C. The initial concentrations of thermolysin and substrate were 0.1  $\mu\text{M}$  and 400  
16  $\mu\text{M}$ , respectively.  $A_{345}$  of the reaction solution was measured continuously. The amount  
17 of FAGLA hydrolyzed was evaluated using the molar absorption difference due to  
18 hydrolysis,  $\Delta\epsilon_{345} = -310 \text{ M}^{-1} \text{ cm}^{-1}$ , at 25°C.<sup>10,11,20)</sup> Reaction rate was determined from  
19 the time course of the decrease of FAGLA.

## 21 **Results**

#### 23 *Effects of thermolysin on ANS fluorescence*

24 Fluorescence spectra of ANS with varying concentrations of thermolysin in 40 mM  
25 HEPES at pH 7.5, 10 mM  $\text{CaCl}_2$  (buffer A), 0 M NaCl were measured (Fig. 1). The shapes  
26 of the fluorescence spectra of ANS measured with 0–2.0  $\mu\text{M}$  of thermolysin were almost  
27 the same, while the fluorescence intensity increased, and the wavelength giving the

Fig. 1

1 maximum fluorescence ( $\lambda_{FI_{max}}$ ) decreased with increasing concentrations of thermolysin  
2 (Fig. 1(A)). The fluorescence intensity at 490 nm ( $FI_{490}$ ) at 2.0  $\mu$ M thermolysin was 133%  
3 of  $FI_{490}$  at 0  $\mu$ M thermolysin (Fig. 1(B)).  $\lambda_{FI_{max}}$  at 2.0  $\mu$ M thermolysin was shorter by 14  
4 nm than  $\lambda_{FI_{max}}$  at 0  $\mu$ M thermolysin (Fig. 1(C)). These results indicate that the  
5 anilidonaphthalene group of ANS binds with thermolysin through hydrophobic  
6 interaction.

### 7 *Effects of ANS on thermolysin activity*

9 FAGLA has been widely used as a substrate for thermolysin.<sup>10-21,30)</sup> However,  $A_{345}$   
10 detection was not available because of the effect of ANS. Accordingly, MOCAC-  
11 PLGL(Dpa)AR was used,<sup>31)</sup> and the products were detected by reversed-phase HPLC (Fig. **Fig. 2**  
12 2). Thermolysin and ANS were pre-incubated at 25°C for 10 min, followed by the  
13 reaction at 25°C. The reaction rates were unchanged with increasing concentration of  
14 ANS. This indicates that ANS neither activates nor inhibits thermolysin activity.

### 15 *Effects of salts on ANS fluorescence in the presence of thermolysin*

16 Fluorescence spectra of ANS in the presence of 1.0  $\mu$ M thermolysin in buffer A with  
17 varying concentrations of NaCl, NaBr, LiCl, or KCl were measured. The change of  $FI_{490}$ ,  
18  $\Delta FI_{490}$ , defined as  $FI_{490}$  in the presence of 1.0  $\mu$ M thermolysin minus  $FI_{490}$  in the absence  
19 of thermolysin, increased with increasing salt concentrations from zero to 4.0 M (Fig. **Fig. 3**  
20 3(A)).  $\Delta FI_{490}$  at 4.0 M NaCl, NaBr, LiCl, and KCl were 249, 204, 168, and 128%,  
21 respectively, of those at 0 M. In the presence of 1.0  $\mu$ M thermolysin,  $\lambda_{FI_{max}}$  at 4.0 M NaCl,  
22 NaBr, LiCl, and KCl were shorter by 17, 15, 11, and 8 nm, respectively, than  $\lambda_{FI_{max}}$  at 0  
23 M NaCl (Fig. 3(B)). In the absence of thermolysin,  $\lambda_{FI_{max}}$  was unchanged (data not shown).  
24 Thus,  $\Delta \lambda_{FI_{max}}$ , defined as  $\lambda_{FI_{max}}$  in the presence of 1.0  $\mu$ M thermolysin minus  $\lambda_{FI_{max}}$  in the  
25 absence of thermolysin, decreased from -6 to -17 nm with increasing NaCl concentration  
26 ([NaCl]), -6 to -15 nm with increasing [NaBr], -6 to -8 nm with increasing [LiCl], and  
27 ([NaCl]), -6 to -15 nm with increasing [NaBr], -6 to -8 nm with increasing [LiCl], and

1 -5 to -8 nm with increasing [KCl] from zero to 4.0 M.  $\Delta FI_{490}$  and  $\Delta \lambda_{FI_{max}}$  at 0–4 M NaCl  
2 are summarized in Table 1. These results indicate that the magnitude of the salt-induced  
3 changes in ANS fluorescence by 1.0  $\mu$ M thermolysin at pH 7.5 was in the order of NaCl,  
4 NaBr, LiCl, and KCl, suggesting that Na<sup>+</sup> ion potently and Li<sup>+</sup> and K<sup>+</sup> ions slightly affect  
5 the ANS fluorescence in the presence of thermolysin, while Cl<sup>-</sup> and Br<sup>-</sup> ions hardly affect  
6 it.

Table 1

#### 8 *Binding of ANS with thermolysin at various NaCl concentrations*

9 To measure the dissociation constants,  $K_d$ , of ANS with thermolysin, fluorescence  
10 area of varying concentrations of ANS was measured in the presence of 1.0  $\mu$ M  
11 thermolysin at 0, 1.0, 2.0, 3.0, and 4.0 M NaCl, pH 7.5. The plot of [ANS]/ $\Delta FI_{area}$  vs.  
12 [ANS] showed non-parallel lines intersecting near at the Y-axis (Fig. 4(A)). Under the  
13 assumption that ANS binds with thermolysin at a single site, the  $K_d$  values at pH 7.5 at 0,  
14 1.0, 2.0, 3.0, and 4.0 M NaCl were calculated to be  $33 \pm 2$ ,  $29 \pm 2$ ,  $23 \pm 4$ ,  $15 \pm 4$ , and  $9 \pm$   
15  $3 \mu$ M, respectively. Relative  $K_d$  was defined as the ratio of the  $K_d$  value at x M NaCl to  
16 that at 0 M NaCl ( $33 \pm 2 \mu$ M). The plot of the reciprocal of relative  $K_d$  vs. [NaCl] indicated  
17 that the reciprocal of relative  $K_d$  value increased with increasing [NaCl] (Fig. 4(B)). The  
18 increase in logarithmic value of the reciprocal of relative  $K_d$  value was not proportional  
19 to [NaCl] (Fig. 4(C)).

Fig. 4

#### 21 *Binding of ANS with thermolysin at various salts*

22 To measure  $K_d$  of ANS with thermolysin, fluorescence area of varying  
23 concentrations of ANS was measured in the presence of 1.0  $\mu$ M thermolysin at 4.0 M  
24 NaCl, NaBr, LiCl, or KCl at pH 7.5. The plot of [ANS]/ $\Delta FI_{area}$  vs. [ANS] showed non-  
25 parallel lines which did not intersect (Fig. 5). The  $K_d$  values at pH 7.5 at 4.0 M NaCl,  
26 NaBr, LiCl, and KCl were calculated to be  $9 \pm 3$ ,  $10 \pm 2$ ,  $12 \pm 3$ , and  $15 \pm 2 \mu$ M, which  
27 were 27–45% of that of  $K_d$  without salts ( $33 \pm 2 \mu$ M), indicating that the  $K_d$  values hardly  
28 depend on salt species at 4 M.

Fig. 5

1  
2 *Effects of pH on ANS fluorescence in the presence of thermolysin*

3 Fluorescence spectra of ANS in the presence of 1.0  $\mu\text{M}$  thermolysin at 0 M NaCl  
4 with varying pH were measured.  $\Delta FI_{490}$ , defined as  $FI_{490}$  in the presence of 1.0  $\mu\text{M}$   
5 thermolysin minus  $FI_{490}$  in the absence of thermolysin, increased with increasing pH from  
6 4.0 to 9.0, and  $\Delta FI_{490}$  at pH 9.0 was 500% of that at pH 4.0 and 170% of that at pH 7.5  
7 (Fig. 6(A)). In the presence of 1.0  $\mu\text{M}$  thermolysin,  $\lambda_{FI_{\text{max}}}$  at pH 9.0 was shorter by 17 nm  
8 than that at pH 4.0 and by 14 nm than that at pH 7.5, while in the absence of thermolysin,  
9 it was stable (Fig. 6(B)). Thus,  $\Delta\lambda_{FI_{\text{max}}}$  decreased from  $-3$  to  $-16$  nm with increasing pH  
10 from 7.0 to 9.0. These results indicate that the magnitude of the change in ANS  
11 fluorescence by 1.0  $\mu\text{M}$  thermolysin at 0 M NaCl increased with increasing pH from 7.0  
12 to 9.0.

Fig. 6

13  
14 *Binding of ANS with thermolysin at various pH*

15 Thermolysin exhibits bell-shaped pH-activity profile with the maximum at pH 6.5  
16 and 7.0.<sup>20</sup> Thermal stability of thermolysin at 70°C was examined at pH 4.5–8.5 (Fig.  
17 7(A)). Relative stability was defined as the ratio of  $k_{\text{obs}}$  at pH 4.5 to that at given pH.  
18 The result indicated that the relative stability was highest at pH 6.5.

Fig. 7

19 To measure  $K_d$  of ANS with thermolysin, fluorescence areas of varying  
20 concentrations of ANS were measured in the presence of 1.0  $\mu\text{M}$  thermolysin at 0 M NaCl,  
21 pH 5.5, 6.5, 7.5, and 8.5. The plot of  $[\text{ANS}]/\Delta FI_{\text{area}}$  vs.  $[\text{ANS}]$  showed non-parallel  
22 lines intersecting at the X-axis (Fig. 7(B)). Under the assumption that ANS binds with  
23 thermolysin at a single site, the  $K_d$  values at 0 M NaCl at pH 5.5, 6.5, 7.5, and 8.5 were  
24  $34 \pm 3$ ,  $31 \pm 2$ ,  $33 \pm 2$ , and  $32 \pm 2$   $\mu\text{M}$ , respectively (Fig. 6(B)), indicating that the  $K_d$   
25 values were unchanged with varying pH from 5.5 to 8.5.

26  
27 **Discussion**

28

1 It has been observed that the effectiveness of monovalent cations of neutral salts to  
2 activate thermolysin is in the order of  $\text{Na}^+ > \text{K}^+ > \text{Li}^+$ , being different to that of the  
3 Hofmeister series ( $\text{Li}^+ > \text{Na}^+ > \text{K}^+$ ).<sup>10,33,34</sup> Based on this evidence, the activation of  
4 thermolysin by neutral salts is not derived from changes in water structure or in the  
5 hydration of the enzyme or substrate. Hence it has been speculated that the salt-induced  
6 activation of thermolysin might be as a result of conformational changes brought about  
7 by the direct interactions of the ions with charged residues on the enzyme.<sup>10-15)</sup>

8 In this study, we showed that ANS binds with thermolysin (Fig. 1), ANS does not  
9 inhibit thermolysin activity (Fig. 2), and NaCl and other salts increase the affinity of  
10 thermolysin for ANS (Figs. 3-5 and Table 1). The degree of the salt-induced changes in  
11 ANS fluorescence by thermolysin was in the order of NaCl, NaBr, LiCl, and KCl (Fig. 3  
12 and Table 1), suggesting that  $\text{Na}^+$  affects ANS fluorescence more potently than  $\text{Cl}^-$  ion. It  
13 also suggests that the effectiveness of monovalent cations of neutral salts on the salt-  
14 induced changes in ANS fluorescence by thermolysin is  $\text{Na}^+ > \text{Li}^+ > \text{K}^+$ , being different  
15 to that of activation of thermolysin ( $\text{Na}^+ > \text{K}^+ > \text{Li}^+$ ). The  $K_d$  values of ANS and  
16 thermolysin at 4.0 M salt were both in the order of KCl, LiCl, NaBr, and NaCl (Fig. 5),  
17 suggesting that the degree of the effects of salts on the interaction of ANS and thermolysin  
18 depends on salt species. From the result that the  $K_d$  values of ANS and thermolysin did  
19 not change with increasing pH from 5.5-8.5 (Fig. 7), we speculate that amino acid  
20 residues with side chains with  $\text{p}K_a$  values of around 5.5-8.5 might not be located in the  
21 ANS-binding site. However, from the results presented in this study, it is difficult to  
22 precisely speculate the mechanism of the effects of salts on the interaction of ANS and  
23 thermolysin.

24 In contrast to that little is known about the mechanism of salt-induced activation of  
25 thermolysin, effects of ions on enzyme activity have been well studied in human  
26 immunodeficiency virus type-1 (HIV-1) protease. HIV-1 protease is a homodimeric  
27 aspartic protease, each containing 99 amino acid residues. Like thermolysin, HIV-1 is  
28 highly activated and stabilized by neutral salts (1-2 M NaCl).<sup>35-37</sup> Recent molecular

1 dynamics simulations and conductivity measurement analysis of HIV-1 protease have  
2 shown that Na<sup>+</sup> binds at least twice as strongly to the surface of HIV-1 protease than K<sup>+</sup>  
3 does.<sup>38,39)</sup>

4 In conclusion, this study suggests that Na<sup>+</sup> and/or Cl<sup>-</sup> ions bind with thermolysin  
5 and affect its binding with ANS. We think that the activation and stabilization of  
6 thermolysin by neutral salts might be due to the binding of ions with thermolysin, and  
7 that ANS might be useful as a fluorescent probe for studying the interaction of ions to  
8 thermolysin. The binding sites for ANS were determined in some proteins.<sup>40,41)</sup> The  
9 elucidation of the binding site of thermolysin for ANS is the next research subject.

3 **Fig. 1.** Effect of Thermolysin on the Fluorescence of ANS.

4 Fluorescence spectra were measured with excitation at 380 nm and emission at  
5 400-600 nm for 25  $\mu$ M ANS in buffer A with various concentrations of thermolysin at  
6 25°C. (A) Fluorescence spectra with 0–2.0  $\mu$ M thermolysin. (B)  $FI_{490}$  with 0–2.0  $\mu$ M  
7 thermolysin. (C) Wavelength giving the maximum fluorescence ( $\lambda_{FI_{max}}$ ). Error bars  
8 indicate SD values of triplicate measurements.

9

10 **Fig. 2.** Effect of ANS on Thermolysin Activity.

11 Thermolysin was pre-incubated for 10 min in the presence and absence of ANS at  
12 25°C at pH 7.5, and the reaction was carried out with 32 nM thermolysin and 20  $\mu$ M  
13 MOCAC-PLGL(Dpa)AR at 25°C at pH 7.5. Error bars indicate SD values of triplicate  
14 measurements.

15

16 **Fig. 3.** Effect of Salts on the Fluorescence of ANS.

17 Fluorescence spectra were measured with excitation at 380 nm and emission at  
18 400-600 nm for 25  $\mu$ M ANS in buffer A, 0–4.0 M NaCl (hollow circle), NaBr (hollow  
19 triangle), LiCl (hollow square) or KCl (hollow diamond) in the presence and absence of  
20 1.0  $\mu$ M thermolysin at 25°C. (A) Change in fluorescence intensity at 490 nm ( $\Delta FI_{490}$ ).  
21  $\Delta FI_{490}$  was defined as the difference in  $FI_{490}$  between the values in the presence and the  
22 absence of 1.0  $\mu$ M thermolysin.  $\Delta FI_{490}$  was plotted against salt concentration. (B) The  
23 wavelength giving the maximum fluorescence ( $\lambda_{FI_{max}}$ ).  $\lambda_{FI_{max}}$  in the presence of 1.0  $\mu$ M  
24 thermolysin was plotted against salt concentration. Error bars indicate SD values of  
25 triplicate measurements.

26

27 **Fig. 4.** Effect of NaCl on the Binding of ANS with Thermolysin.

28  $\Delta FI_{area}$  was defined as the difference in  $FI_{490}$  between the values in the presence

1 and the absence of 1.0  $\mu\text{M}$  thermolysin.  $\Delta FI_{\text{area}}$  were measured with 10–250  $\mu\text{M}$  ANS  
2 in the presence of 0 (solid circle) 1.0 (hollow diamond), 2.0 (hollow square), 3.0  
3 (hollow circle), or 4.0 M (hollow circle) NaCl.  $[\text{ANS}]/\Delta FI_{\text{area}}$  vs.  $[\text{ANS}]$  plot is  
4 shown. (B) Effect of NaCl on the dissociation constants ( $K_d$ ). Relative  $K_d$  was defined as  
5 the ratio of the  $K_d$  value at x M NaCl to that at 0 M NaCl ( $30 \pm 2 \text{ mM}^{-1}$ ). (C) Logarithmic  
6 relationship of  $K_d$  with  $[\text{NaCl}]$ . Error bars indicate SD values of triplicate  
7 measurements.

8

9 **Fig. 5.** Effect of Salts on the Binding of ANS with Thermolysin.

10  $\Delta FI_{\text{area}}$  were measured with 10–250  $\mu\text{M}$  ANS in the presence of 4 M NaCl  
11 (hollow circle), NaBr (hollow triangle), LiCl (hollow square) or KCl (hollow diamond)  
12 and in the absence of salts (solid circle).  $[\text{ANS}]/\Delta FI_{\text{area}}$  vs.  $[\text{ANS}]$  plot is shown. One  
13 of the representative data is shown.

14

15 **Fig. 6.** Effect of pH on the Fluorescence of ANS.

16 Fluorescence spectra were measured with excitation at 380 nm and emission at  
17 400–600 nm for 25  $\mu\text{M}$  ANS in 50 mM acetate-NaOH buffer at pH 3.5, 4.0, and 4.5, 50  
18 mM MES-NaOH buffer at pH 5.0, 5.5 and 6.5, 50 mM HEPES-NaOH buffer at pH 7.5  
19 and 8.0 and 50 mM AMPSO-NaOH buffer at pH 8.5 and 9.0, each containing 10 mM  
20  $\text{CaCl}_2$  at 25°C. (A) Change in fluorescence intensity at 490 nm ( $\Delta FI_{490}$ ).  $\Delta FI_{490}$  was  
21 defined as the difference in  $FI_{490}$  between the values in the presence and the absence of  
22 1.0  $\mu\text{M}$  thermolysin.  $\Delta FI_{490}$  was plotted against pH. (B) The wavelength giving the  
23 maximum fluorescence ( $\lambda_{FI_{\text{max}}}$ ).  $\lambda_{FI_{\text{max}}}$  in the presence (hollow square) and the absence  
24 (hollow circle) of 1.0  $\mu\text{M}$  thermolysin was plotted against pH. Error bars indicate SD  
25 values of triplicate measurements.

26

27 **Fig. 7.** Effect pH on the Binding of ANS with Thermolysin.

28 (A) pH-stability profile. Thermolysin (1.0  $\mu\text{M}$ ) in 40 mM HEPES-NaOH, 10 mM

1 CaCl<sub>2</sub>, and 0–4.0 M NaCl at pH 7.5 was incubated at 70°C for specified durations. The  
2 experimental conditions for FAGLA hydrolysis were as described in the Materials and  
3 methods section. Relative stability of thermolysin variants was defined as the ratio of  
4 the first-order rate constant,  $k_{\text{obs}}$ , of the thermal inactivation at 0 M NaCl ( $1.2 \pm 0.1 \times 10^{-4}$   
5  $\text{s}^{-1}$ ) to that at x M NaCl. (B) [ANS]/ $\Delta FI_{\text{area}}$  vs. [ANS] plot. Symbols for pH: 5.5,  
6 hollow circle; 6.5, hollow triangle; 7.5, hollow square; and 8.5, solid circle. Error bars  
7 indicate SD values of triplicate measurements.

1 **Table 1.** Effect of Salts on Thermolysin Acitivity and Change in ANS Fluorescence by  
 2 Thermolysin.

3

4	Salt	Relative activity <sup>a</sup>	$\Delta FI_{490}$ <sup>b</sup>	$\Delta \lambda_{FI_{max}}$ <sup>b</sup>
5	no salt	1.0	2.2	-6
6	LiCl 1 M	1.1	2.9	-10
7	2 M	1.5	3.0	-10
8	3 M	3.4	3.2	-11
9	4 M	4.5	3.6	-11
10	NaCl 1 M	1.9	3.0	-8
11	2 M	3.6	3.7	-9
12	3 M	6.9	5.0	-10
13	4 M	13	5.9	-17
14	KCl 1 M	1.7	2.5	-6
15	2 M	3.0	2.2	-7
16	3 M	5.2	2.8	-11
17	4 M	9.0	2.6	-8
18	NaBr 1 M	1.8	2.7	-11
19	2 M	3.2	3.1	-12
20	3 M	5.8	4.2	-15
21	4 M	11	4.7	-15

22

23 <sup>a</sup> Ref. 15. The relative activities are the ratios of the specificity constant,  $k_{cat}/K_m$ , in the  
 24 hydrolysis of FAGLA at x M NaCl to that at 0 M NaCl, in 40 mM Tris-HCl buffer at pH  
 25 7.5, 10 mM CaCl<sub>2</sub> at 25°C. The  $k_{cat}/K_m$  value at no salt is  $2.2 \times 10^4 \text{ M}^{-1} \text{ s}^{-1}$ .

26 <sup>b</sup> The  $\Delta FI_{490}$  and  $\Delta \lambda_{FI_{max}}$  were determined based on the results shown in Fig. 3.
