(Received 20 March 2007; published 22 June 2007)

In terms of mass generation in the strong interaction without chiral symmetry breaking, we perform the first study for light scalar-quarks \(\phi\) (colored scalar particles with \(3_L\) or idealized diquarks) and their color-singlet hadronic states using quenched SU(3) lattice QCD with \(\beta = 5.70\) (i.e., \(a \approx 0.18\) fm) and lattice size \(16^3 \times 32\). We investigate “scalar-quark mesons” \(\phi^+ \phi\) and “scalar-quark baryons” \(\phi \bar{\phi} \phi\) as the bound states of scalar-quarks \(\phi\). We also investigate the color-singlet bound states of scalar-quarks \(\phi\) and quarks \(\psi\), i.e., \(\phi^+ \psi\), \(\psi^+ \phi\), and \(\phi \bar{\phi} \psi\), which we name “chimera hadrons.” All the new-type hadrons including \(\phi\) are found to have a large mass even for zero bare scalar-quark mass \(m_\phi = 0\) at \(a^{-1} \approx 1\) GeV. We find a “constituent scalar-quark/particle” for both scalar-quark hadrons and chimera hadrons. Namely, the mass of the new-type hadron composed of \(m \phi\)'s and \(n \psi\)'s, \(M_{m\phi+n\psi}\), approximately satisfies \(M_{m\phi+n\psi} \approx mM_\phi + nM_\psi\), where \(M_\phi\) and \(M_\psi\) are the constituent scalar-quark and quark masses, respectively. We estimate the constituent scalar-quark mass \(M_\phi\) for \(m_\phi = 0\) at \(a^{-1} \approx 1\) GeV as \(M_\phi \approx 1.5\)–1.6 GeV, which is much larger than the constituent quark mass \(M_\psi\) \(\approx 400\) MeV in the chiral limit. Thus, scalar quarks acquire a large mass due to large quantum corrections by gluons in the systems including scalar quarks. Together with other evidences of mass generation of glueballs and charmonia, we conjecture that all colored particles generally acquire a large effective mass due to dressed gluon effects. In addition, the large mass generation of pointlike colored scalar particles indicates that plausible diquarks used in effective hadron models cannot be described as the pointlike particles and should have a much larger size than \(a \approx 0.2\) fm.

I. INTRODUCTION

The origin of mass has been one of the fundamental and fascinating subjects in physics for a long time. A standard interpretation of mass origin is the Yukawa interaction with the Higgs field [1], of which observation is one of the most important aims of the Large Hadron Collider (LHC) experiment at CERN. However, the mass of Higgs origin is only about 1% of total mass in the world, because the Higgs interaction only provides the current quark mass (less than 10 MeV for light quarks) and the lepton mass (0.51 MeV for electrons) [2]. On the other hand, apart from unknown dark matter, about 99% of mass of matter in the world originates from the strong interaction, which actually provides the large constituent quark mass \(M_\psi = (300–400)\) MeV [3]. Such a dynamical fermion-mass generation in the strong interaction can be interpreted as spontaneous breaking of chiral symmetry, which was first pointed out by Nambu et al. [4]. According to the chiral symmetry breaking, light quarks are considered to have a large constituent quark mass of about 400 MeV [5,6]. In terms of the mass-generation mechanism, it is interesting to investigate high density and/or high temperature systems, because chiral symmetry is expected to be restored in the system [7–9]. Several theoretical studies suggest that such a restoration affects the hadron nature [8–11]. Actually, the experiments at CERN SPS [12] and KEK [13] indicate the change of nature of the vector mesons \(\rho, \omega,\) and \(\phi\) in the finite density system. These experiments are important for the study of the mass generation originated from chiral symmetry breaking. In this way, the origin of mass and its related topics, including the Higgs-particle search at LHC and chiral symmetry breaking in QCD, are energetically studied in both sides of theories and experiments.

Then, a question arises: Is there any mechanism of dynamical mass generation without chiral symmetry breaking? To answer this question, we note the following examples supporting the existence of such a mechanism. One example is gluons, i.e., colored vector particles in QCD. While the gluon is massless in perturbation QCD, nonperturbative effects due to the self-interaction of gluons seem to generate a large effective gluon mass as \((0.5–1.0)\) GeV, which is measured in lattice QCD [14,15]. Actually, glueballs, which are composed of gluons, have a large mass, e.g., about 1.5 GeV [16,17] even for the lightest glueball \((J^P = 0^+\) ), and the scalar meson \(f_0(1500)\) is one of the candidates of the lowest \(0^+\) glueball in the experimental side [2]. Another example is charm quarks. The current mass of charm quarks is about 1.2 GeV at the renormalization point \(\mu = 1\) GeV [2]. In the quark model, however, the constituent charm-quark mass which reproduces masses of charmonia is set to be about 1.6 GeV [3]. The about 400 MeV difference between the current and the constituent charm-quark masses can be explained as dynamical mass generation without chiral symmetry breaking, since there is no chiral symmetry for such a heavy-quark system.

\(^*\)iida@yukawa.kyoto-u.ac.jp; iida@rcnp.osaka-u.ac.jp
These examples suggest that there is another type of mass generation without chiral symmetry breaking and the Higgs mechanism. Then, we conjecture that, even without chiral symmetry breaking, large dynamical mass generation generally occurs in the strong interaction, i.e., all colored particles have a large effective mass generated by dressed gluon effects. This is one of the main motivations of the present study on the mass generation of the hadronic systems including light scalar quarks, which do not have the chiral symmetry.

The study is also motivated by the “diquark picture” of hadrons [18–21]. The diquark is made of two quarks which are strongly correlated in the color antitriplet 3 channel, where the one-gluon-exchange interaction between two quarks is most attractive. Sometimes, diquarks are treated as pointlike objects or local boson fields. Degrees of freedom of diquarks seem to be important in some aspects of hadron physics. For example, nucleon structure functions can be explained by the model in which the nucleon is the admixture of a diquark and a quark [18,19]. Diquarks are also important for hadron spectra [20,21]. In an extremely high density system, diquark condensation is considered to appear due to the attractive interaction of one-gluon exchange in the color 3 channel. Such a phase is called the color superconductivity phase [22,23] and it may exist in the interior of neutron stars. However, the properties of diquarks such as the size and the mass are not well understood, in spite of the frequent use of diquarks in hadron physics. We note that the pointlike limit of diquarks in the color 3 channel can be regarded as the scalar quark in a fundamental representation of SU(3), in scalar QCD [24]. Therefore, the theoretical study of scalar quarks with a reliable method is expected to be a good test place to check the validity of the pointlike diquark picture.

In this paper, according to these motivations, we study the light scalar quark belonging to the fundamental representation of SU(3), and their color-singlet hadronic states using quenched SU(3) lattice QCD [25]. We investigate “scalar-quark hadrons,” which are the color-singlet bound states of scalar-quarks \( \phi \), and “chimera hadrons,” which are the bound states of \( \phi \) and (ordinary) quarks \( \psi \). Using the standard technique of the lattice gauge theory, we calculate the temporal correlators of these new-type hadrons at the quenched level, and extract their mass of the lowest energy state from the correlators. As a result, we find a large mass of the hadron including scalar-quarks \( \phi \). Also we find the “constituent scalar-quark/quark picture” for all the new-type hadrons. Namely, the mass of the new-type hadron which is composed of \( m \phi \)'s and \( n \psi \)'s, \( M_{m\phi+n\psi} \), satisfies \( M_{m\phi+n\psi} \approx mM_\phi + nM_\psi \), where \( M_\phi \) and \( M_\psi \) are the constituent scalar-quark and quark masses, respectively. The constituent scalar-quark mass \( M_\phi \) estimated from the masses of these new-type hadrons is found to be much larger than the constituent quark mass \( M_\psi \approx 400 \text{ MeV} \) for light quarks. This result suggests that, in the system of colored scalar particles, there occurs large mass generation in the strong interaction without chiral symmetry breaking.

The article is organized as follows. In Sec. II, the new states including scalar quarks, “scalar-quark hadrons” and “chimera hadrons,” are introduced. In Sec. III, we present the formalism of lattice QCD including scalar quarks, the setup of the lattice calculations, and the method to extract the masses of the new-type hadrons. In Sec. IV, we show the numerical results of the scalar-quark hadrons, i.e., scalar-quark mesons \( \phi^4 \phi \) and scalar-quark baryons \( \phi\phi\phi \), and investigate the constituent scalar-quark picture and mass generation of scalar quarks. In Sec. V, we show the numerical results of the chimera hadrons, i.e., chimera mesons \( \phi^4 \psi \) and chimera baryons, \( \psi\psi\phi \) and \( \phi\phi\psi \), and analyze them in terms of the constituent scalar-quark/quark picture and their structure. Sec. VI is devoted to conclusion and discussion.

II. NEW STATES INCLUDING SCALAR QUARKS: SCALAR-QUARK HADRONS AND CHIMERA HADRONS

In this section, we explain the new-type hadrons introduced in this study: various color-singlet systems including light scalar-quarks \( \phi \). We call the color-singlet state composed only of scalar-quarks \( \phi \) as a “scalar-quark hadron”: the scalar-quark meson is composed of a scalar quark and an anti-scalar-quark, \( \phi^4 \phi \), and the scalar-quark baryon is made of three scalar quarks, \( \phi\phi\phi \). The scalar-quark meson field \( M_i(x) \) and the scalar-quark baryon field \( B_i(x) \) can be expressed by gauge-invariant local operators as

\[
M_i(x) = \Gamma^{ij}_M \phi^{k\dagger}_i(x) \phi^j_k(x),
\]

\[
B_i(x) = \Gamma^{ijk}_B \epsilon_{abc} \phi^{k\dagger}_a(x) \phi^i_b(x) \phi^j_c(x),
\]

where the scalar-quark field \( \phi_a(x) \) \((a = 1, 2, 3)\) belongs to the fundamental \( (3_i) \) representation of \( SU(3)_c \). In the above equations, \( a, b, \) and \( c \) denote the color indices, and \( \epsilon_{abc} \) is the antisymmetric tensor for color indices. Here, we have generally introduced different species of scalar quarks, which leads to the “scalar-quark flavor” degrees of freedom. In Eqs. (1) and (2), \( i, j, \) and \( k \) denote the scalar-quark flavor indices, and \( \Gamma^{ij}_M \) and \( \Gamma^{ijk}_B \) are some tensors on the scalar-quark flavor. We note that, for the local-operator description of scalar-quark baryons, the number \( N^{scalar}_f \) of the scalar-quark flavor should be \( N^{scalar}_f \geq 3 \). Actually, for \( N^{scalar}_f \leq 2 \), the local scalar-quark baryon operator vanishes due to the antisymmetric tensor \( \epsilon_{abc} \), although a non-local-operator description is possible for scalar-quark baryons. In contrast, scalar-quark mesons can be described with local operators at any number of \( N^{scalar}_f \) (\( \geq 1 \)).

We call the color-singlet state made of scalar-quarks \( \phi \) and (ordinary) quarks \( \psi \) as a “chimera hadron”: chimera mesons \( \phi^4 \psi \) and chimera baryons, \( \psi\psi\phi \) and \( \phi\phi\psi \). The
chimera meson field $C_M^a(x)$ and the chimera baryon field, $C_B^a(x)$, can be expressed by gauge-invariant local operators as

$$C_M^a(x) = \phi_{\lambda}^a(x)\psi_{\alpha}^a(x),$$  \hspace{1cm} (3)

$$C_B^a(x) = \epsilon_{abc} (\psi_{\alpha}^b(x) C M_{\gamma}^b \psi_{\alpha}^c(x)) \phi_{\lambda}^c(x),$$  \hspace{1cm} (4)

$$C_B^a(x) = \Gamma^a_{\beta} \epsilon_{abc} \phi_{\lambda}^b(x) \phi_{\lambda}^c(x) \psi_{\alpha}^c(x),$$  \hspace{1cm} (5)

where $\alpha$ denotes the spinor index, $\Gamma^a_{\beta}$ is some tensor on the scalar-quark flavor. We also note that, for the local-operator description of the $\phi\phi\psi$-type chimera baryon, the scalar-quark number $N_{S}^c$ is to be $N_{S}^c \geq 2$. For $N_{S}^c = 1$, the local operator of the $\phi\phi\psi$-type chimera baryon vanishes due to the antisymmetric tensor $\epsilon_{abc}$ like the scalar-quark baryon case, although a non-local-operator description is possible. On the other hand, chimera mesons $\phi^\dagger\psi$ and chimera baryons $\psi\psi\phi$ can be described with local operators at any number of $N_{S}^c \geq 1$.

We comment on the single-flavor case of the scalar quark. In this case, from the symmetric property of bosons $\phi$ and the antisymmetric property of the color quantum number, the space-time coordinates of bosons $\phi$ are to be antisymmetrized in scalar-quark baryons and the solid line corresponds to the (ordinary) quark $\phi$, and the arrow denotes the current of the color in fundamental representation. As for the scalar-quark meson, we only consider the connected diagram, i.e., nonsinglet states of the scalar-quark flavor. For scalar-quark baryons, no disconnected diagram appears because of the color conservation.

gate nonsinglet states of the scalar-quark flavor, and therefore the disconnected diagram does not appear in our calculation. For scalar-quark baryons, no disconnected diagram appears at the quenched level like ordinary baryons, because of the conservation law of the color quantum number. (Note that the scalar-quark $\phi$ belongs to the fundamental representation, $3_c$.)

In Fig. 2, we show the diagrams for chimera hadrons, corresponding to the two-point correlator of the chimera meson ($\phi^\dagger\psi$) and that of the chimera baryon ($\psi\psi\phi$). The dotted line corresponds to the scalar-quark $\phi$ and the solid line corresponds to the (ordinary) quark $\psi$. Also for chimera mesons and chimera baryons, no disconnected diagram appears at the quenched level, because of the conservation law of the color quantum number and the quark number. In fact, disconnected diagrams appear only for the flavor-singlet scalar-quark meson.

We note that the statistical property for these new-type hadrons is rather different from that for ordinary hadrons. For example, the scalar-quark baryon $\phi\phi\phi$ is a boson and the chimera meson $\phi^\dagger\psi$ is a fermion, while ordinary baryons are fermions and ordinary mesons are bosons. In Table I, we summarize the names, Lorentz properties, and gauge-invariant local operators for the new-type hadrons.

FIG. 2. Diagrams for chimera hadrons corresponding to (a) the two-point correlator of chimera mesons ($\phi^\dagger\psi$) and (b) that of chimera baryons ($\psi\psi\phi$). The dotted line corresponds to the scalar-quark $\phi$ and the solid line corresponds to the (ordinary) quark $\psi$. For chimera mesons and chimera baryons, no disconnected diagram appears because of the color and the quark-number conservation.
We study the mass generation of scalar quarks by investigating the various color-singlet systems including scalar quarks in the lattice gauge theory.

III. FORMALISM AND SETUP OF LATTICE QCD FOR SCALAR QUARKS

In this section, we present the lattice QCD formalism for scalar quarks and the setup for the actual calculation. To include scalar-quarks \( \phi \) together with quarks \( \psi \) and gluons \( A_\mu \equiv A_\mu^a T^a \) in QCD, we adopt the generalized QCD Lagrangian density

\[
L = -\frac{i}{2} G_{\mu \nu}^{a} G^{a \mu \nu} + \mathcal{L}_V + \mathcal{L}_{SQ},
\]

\[
\mathcal{L}_V = \bar{\psi}(i \gamma^\mu D_\mu \phi - m_\phi) \psi,
\]

\[
\mathcal{L}_{SQ} = \text{tr}(D_\mu \phi)^\dagger (D^\mu \phi) - m^2_\phi \text{tr} \phi^\dagger \phi,
\]

in the continuum limit in the Minkowski space. Here, the scalar-quark field \( \phi = (\phi_1, \phi_2, \phi_3) \) belongs to the fundamental \( (3, 1) \) representation of the color SU(3) like the quark field \( \psi = (\psi_1, \psi_2, \psi_3) \). \( m_\phi \) is the bare mass of quarks and is expressed as a diagonal matrix in the flavor space. Similarly, \( m_{\bar{\phi}} \) is the bare mass of scalar quarks, and is expressed as a diagonal matrix in the scalar-quark flavor space. In this study, all the quarks are taken to have the same bare mass \( m_\phi \), and all the scalar quarks are taken to have the same bare scalar-quark mass \( m_{\bar{\phi}} \).

\( G_{\mu \nu}^{a} \) denotes the field strength tensor defined as

\[
G_{\mu \nu}^{a} \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g f^{abc} A_\mu^b A_\nu^c,
\]

where \( f^{abc} \) is the structure constant of SU(3), and \( \gamma^\mu D_\mu \) denotes the covariant derivative,

\[
D_\mu \equiv \partial_\mu - ig A_\mu^a T^a.
\]

In the lattice calculation, we discretize this action in the Euclidean metric. For the gluon sector, we adopt the standard plaquette action [29],

\[
S_G = \frac{\beta}{N_c} \sum_{x, \mu, \nu} \text{Re} \text{Tr} \{ 1 - P_{\mu \nu}(x) \},
\]

with \( \beta = 2N_c/g^2 \). The plaquette \( P_{\mu \nu}(x) \) is given by

\[
P_{\mu \nu}(x) = U_\mu (x) U_\nu (x + \hat{\mu}) U_\nu^\dagger (x) (x + \hat{\nu}) U_\mu^\dagger (x),
\]

where \( U_\mu (x) \in \text{SU}(N_c) \) is the link variable, corresponding to the gluon field as \( U_\mu (x) \equiv \exp(i a g A_\mu (x)) \) near the continuum limit. \( \hat{\mu} \) denotes the unit vector of the direction \( \mu \) on the lattice.

For the quark part, we use the Wilson fermion action [29],

\[
S_F = \sum_{x, y} \bar{\psi}(x, y) K(x, y) \psi(y),
\]

\[
K(x, y) = \delta_{x, y} - \kappa \sum_\mu \{ (1 - \gamma_\mu) U_\mu (x) \delta_{x + \hat{\mu}, y} + (1 + \gamma_\mu) U_\mu^\dagger (y) \delta_{x, y + \hat{\mu}} \},
\]

where \( \kappa \) is the hopping parameter related to the bare quark mass \( m_\phi \). The Wilson fermion action includes \( O(a) \) discretization error, which can be reduced by using the \( O(a) \)-improved fermion action [30,31].

For scalar quarks, we take the local and simplest gauge-invariant action,

\[
S_{SQ} = \sum_{x, y} \phi^\dagger (x) \left\{ - \sum_\mu \{ \delta_{x + \hat{\mu}, y} U_\mu (x) + \delta_{x, y - \hat{\mu}} U_\mu^\dagger (y) - 2 \delta_{x y} 1 \} + m^2_{\bar{\phi}} \delta_{x y} 1 \right\} \phi(y).
\]

Note that the scalar-quark action only includes \( O(a^2) \) discretization error, which is the same order of that in the gauge action and is higher order than that of the Wilson fermion action. In contrast to the fermion case, the indirect bare-mass parameter such as \( \kappa \) for quarks is not needed to calculate the scalar-quark system, since no doubler appears and the Wilson term is not necessary for the scalar field. Therefore, we can directly use the bare mass \( m_\phi \) for the lattice calculation of scalar quarks.

In this lattice action, the scalar-quark \( \phi \) is introduced as a local field on the lattice with spacing \( a \), and therefore the scalar-quark \( \phi \) can be regarded as an elementary local field at the renormalization point \( a^{-1} \) or a pointlike (composite) object with the intrinsic size of \( O(a) \). When the scalar-
We calculate the following temporal correlator $G(t)$ of the hadronic operator $O(x, t)$,

$$G(t) = \frac{1}{V} \sum_x \langle \hat{O}(x, t) \hat{O}^\dagger(\hat{0}, 0) \rangle,$$

where the total momentum is projected to be zero. To extract the lowest-state mass $M_0$ of a hadron, we fit the temporal correlator by the single exponential function $G_{\text{fit}}(t) \equiv A \exp[-M_0 t]$ in the region $[t_{\text{min}}, t_{\text{max}}]$ where the lowest energy state dominates. For the determination of the fit range, we construct so-called effective mass,

$$m_{\text{eff}}(t) \equiv \ln \frac{G(t)}{G(t + 1)}.$$

If $G(t)$ is dominated by the lowest state with mass $M_0$ in a certain region for large $t$, then $m_{\text{eff}}(t) \approx M_0$ for the $t$ region. In other words, if there is a plateau region of $m_{\text{eff}}(t)$ for large $t$, the correlator is dominated by the lowest energy state for the $t$ region. Therefore, we set the fit region $[t_{\text{min}}, t_{\text{max}}]$ of the correlator from the plateau region $[t_{\text{min}}, 10]$ of the effective mass. Figure 3 is the examples of effective masses for (a) scalar-quark mesons $\phi \bar{\phi}$, (b) scalar-quark baryons $\phi \phi \bar{\phi}$, (c) chimera mesons $\phi \phi \bar{\phi}$, (d) chimera baryons $\psi \psi \bar{\phi}$, and (e) chimera baryons $\phi \phi \bar{\psi}$. In these effective masses, we can see the plateau regions. We note here that the error estimate is done by the jackknife method for all the data in this study.

In this way, using the standard lattice QCD technique, we can extract the lowest mass for the new-type hadrons including scalar quarks like the ordinary hadrons.

**IV. RESULTS FOR SCALAR-QUARK HADRONS**

In this section, we show lattice results for the mass of scalar-quark hadrons, namely, scalar-quark mesons $\phi \bar{\phi}$ and scalar-quark baryons $\phi \phi \bar{\phi}$. Figure 4(a) shows the scalar-quark meson mass $M_{\phi \bar{\phi}}$ plotted against the bare scalar-quark mass $m_\phi$. In Fig. 4(a), we find a large mass of

TABLE III. Masses of $\pi$ (pseudoscalar meson), $\rho$ (vector meson), and $N$ (nucleon) calculated on the lattice for each hopping parameter $\kappa$. The error estimate is done by the jackknife method. $\chi^2$ per degrees of freedom $N_{\text{df}}$ and the rough estimate of the bare quark mass $m_\phi$ are added. The unit is GeV.
about 3 GeV for the scalar-quark meson, even for zero bare scalar-quark mass, $m_\phi = 0$. This scalar-quark meson mass is rather large compared to the ordinary low-lying mesons composed of light quarks. Figure 4(b) shows the scalar-quark baryon mass $M_{\phi\phi\phi}$ plotted against $m_\phi$. In Fig. 4(b), we find also a large mass of about 4.7 GeV for the scalar-quark baryon, even for zero bare scalar-quark mass. The numerical data for these figures are listed in Table IV.

From the data of these scalar-quark hadrons, the “constituent scalar-quark picture” seems to be satisfied, i.e., $M_{\phi^+\phi} \approx 2M_\phi$ and $M_{\phi\phi\phi} \approx 3M_\phi$, where $M_\phi$ is the constituent (dynamically generated) scalar-quark mass and is 1.5–1.6 GeV. Thus, in the scalar-quark hadron systems, there occurs large mass generation of scalar quarks (large quantum correction to the bare scalar-quark mass) in the strong interaction without chiral symmetry breaking.

In the quark system, the propagator of quarks at $m_\phi = 0$ cannot be calculated practically in lattice QCD simulations. However, in the scalar-quark system, we can calculate the propagator of scalar quarks even at $m_\phi = 0$. Figures 4(c) and 4(d) show the scalar-quark meson mass squared $M_{\phi^+\phi}^2$ and scalar-quark baryon mass squared $M_{\phi\phi\phi}^2$ including the results for $m_\phi^2 < 0$ plotted against $m_\phi^2$. Table V shows the lattice data for $m_\phi^2 < 0$. As a remarkable fact, the lattice calculation can be performed even with $m_\phi^2 < 0$, because the large quantum correction makes the hadron masses positive even with such a “tachyonic” bare scalar-quark mass.

In Figs. 4(c) and 4(d), we find the linear $m_\phi^2$-dependence of $M_{\phi^+\phi}^2$ and $M_{\phi\phi\phi}^2$. More precisely, we find the approximate relations

$M_{\phi^+\phi}^2 \propto m_\phi^2$ 

$M_{\phi\phi\phi}^2 \propto m_\phi^2$
FIG. 4. (a) The scalar-quark meson mass $M_{\phi\phi\phi}$ and (b) the scalar-quark baryon mass $M_{\phi\phi\phi}$ plotted against the bare scalar-quark mass $m_{\phi}$. Even at $m_{\phi} = 0$, large masses of about 3 and 4.7 GeV are observed for the scalar-quark meson and the scalar-quark baryon, respectively. (c) The scalar-meson mass squared $M_{\phi\phi\phi}^2$ and (d) the scalar-quark baryon mass squared $M_{\phi\phi\phi}^2$ are plotted against $m_{\phi}$ in both cases of $m_{\phi}^2 \geq 0$ and $m_{\phi}^2 < 0$. Calculations can be performed even with $m_{\phi}^2 \leq 0$. Almost linear $m_{\phi}^2$-dependence is observed for both scalar-quark mesons and scalar-quark baryons.

### TABLE V. The mass of scalar-quark hadrons in the region of $m_{\phi}^2 < 0$. The unit of mass is GeV. Notations are the same as those in Table IV.

tum correction for the scalar field as

These relations can be naturally explained with the quantum correction for the scalar field as

\[ M_{\phi^1,\phi}^2 \approx 4m_{\phi}^2 + \text{const} \tag{19} \]

and

\[ M_{\phi,\phi^1,\phi}^2 \approx 9m_{\phi}^2 + \text{const}. \tag{20} \]

These relations can be naturally explained with the quantum correction for the scalar field as

\[ M_{\phi}^2 \approx m_{\phi}^2 + \Sigma_{\phi}, \tag{21} \]

for obtaining the scalar-quark propagator does not converge in the region about \( m_{\phi}^2 < -(1.2 \text{ GeV})^2 \).

To enforce the validity of the constituent scalar-quark picture, we show in Fig. 5(c) the ratio of the scalar-quark baryon mass to the scalar-quark meson mass, plotted against the bare scalar-quark mass \( m_{\phi}^2 \). Except for the large negative region of \( m_{\phi}^2 \), we find the relation of the constituent scalar-quark picture as

\[ \frac{M_{\phi,\phi^1,\phi}}{M_{\phi^1,\phi}} \approx 1.5 \left( \frac{3}{2} \right) \tag{22} \]

where \( 3/2 \) is the ratio of the “constituent number” of the scalar quarks in the new-type hadrons.

V. RESULTS FOR CHIMERA HADRONS

Next, we show lattice QCD results for the mass of chimera hadrons: chimera mesons \( \phi^1 \psi \) and chimera baryons, \( \psi\psi\phi \) and \( \phi\phi\phi \). Figures 6–8 show the mass of chimera mesons \( \phi^1 \psi \) and chimera baryons, \( \psi\psi\phi \) and \( \phi\phi\phi \), plotted against the pion mass \( M_{\pi} \). The panels (a), (b), (c), and (d) of each figure are the masses of each hadron at \( m_{\phi} = 0, 110, 220, \) and 330 MeV, respectively, plotted against \( M_{\pi}^2 \). The data at \( M_{\pi}^2 = 0 \) is obtained from linear extrapolation and the solid lines denote the best-fit linear functions of the data. In panel (e) of each figure, the central values of panels (a), (b), (c), and (d) are plotted all
FIG. 6. The mass of chimera mesons, $M_{\phi^\dagger \psi}$, plotted against pion mass squared $M_\pi^2$ in the unit of GeV$^2$. (a), (b), (c), and (d) are $M_{\phi^\dagger \psi}$ at $m_\phi = 0, 110, 220, \text{and} 330 \text{MeV}$, respectively, plotted against $M_\pi^2$. The data at $M_\pi^2 = 0$ is obtained from linear extrapolation, and the solid line denotes the best-fit linear function of the data. In (e), the central values of (a), (b), (c), and (d) are plotted all together. Different symbols correspond to the different bare scalar-quark mass $m_\phi$ (circle: $m_\phi = 0$; square: $m_\phi = 0.11 \text{GeV}$; triangle: $m_\phi = 0.22 \text{GeV}$; diamond: $m_\phi = 0.33 \text{GeV}$). Table VI is the summary of the mass of chimera hadrons.

In Fig. 6, the large mass of chimera mesons $\phi^\dagger \psi$ can be seen. The extrapolated value of $M_{\phi^\dagger \psi}$ at $M_\pi^2 = 0$ and $m_\phi = 0$ is 1.86 GeV. Similar to scalar-quark hadron masses, $M_{\phi^\dagger \psi}$ is very large compared to ordinary low-lying mesons composed of light quarks. Also, we find a constituent scalar-quark/quark picture, i.e., $M_{\phi^\dagger \psi} \approx M_\phi + M_\psi$ for $M_\phi \approx 1.5 \text{GeV}$ and $M_\psi \approx 0.4 \text{GeV}$. The constituent scalar-quark mass $M_\phi \approx 1.5 \text{GeV}$ is consistent with that estimated from scalar-quark hadron masses. Concerning the dependence of $m_\phi$ and $M_\pi$, $m_\phi$ dependence is rather weak compared to $M_\pi$. In fact, the mass difference between $M_{\phi^\dagger \psi}(m_\phi = 0, M_\pi^2 = 0)$ and $M_{\phi^\dagger \psi}(m_\phi = 0.33 \text{GeV}, M_\pi^2 = 0)$ is only 43 MeV, while the difference of $m_\phi$ is 330 MeV [$M(m_\phi = \alpha, M_\pi^2 = \beta)$ denotes the mass $M$ at $m_\phi = \alpha$ and $M_\pi = \beta$]. On the other hand, the mass difference between $M_{\phi^\dagger \psi}(m_\phi = 0, M_\pi^2 = 0)$ and $M_{\phi^\dagger \psi}(m_\phi = 0, M_\pi^2 = (0.75 \text{GeV})^2)$ is about 120 MeV. This value is the same order of the difference of $m_\phi$, $\delta m_\phi \approx 190 \text{MeV}$, estimated from the relation $2m_\phi \alpha = 1/\kappa - 1/\kappa_c$. Together, different symbols of panel (e) of each figure correspond to the different bare scalar-quark mass $m_\phi$ (circle: $m_\phi = 0$; square: $m_\phi = 0.11 \text{GeV}$; triangle: $m_\phi = 0.22 \text{GeV}$; diamond: $m_\phi = 0.33 \text{GeV}$).
from linear extrapolation. Error estimate is done by the jackknife method.

FIG. 7. The mass of chimera baryons, \( M_{\psi \phi \phi} \), plotted against pion mass squared \( M_\pi^2 \) in the unit of GeV\(^2\). The notation, unit, and notices are the same as those of Fig. 6.
As for the chimera baryon $\psi\psi\phi$, the same tendency as chimera mesons $\phi^1\psi$ is observed in Figs. 6 and 7 in terms of $m_\phi$ and $M_\pi$ dependence. We find also the constituent scalar-quark/quark picture: $M_{\psi\psi\phi} \approx M_\phi + 2M_\phi$ for $M_\phi \approx 1.5$ GeV and $M_\phi \approx 400$ MeV. $m_\phi$-dependence of $M_{\psi\psi\phi}$ is weak and is almost the same as that of the chimera meson. For $M_\pi$-dependence, the difference between $M_{\phi\phi\phi}(m_\phi = 0, M_\pi^2 = 0)$ and $M_{\phi\phi\phi}(m_\phi = 0, M_\pi^2 = (0.75 \text{ GeV})^2)$ is about 320 MeV. This is about the same value of $2\Delta m_\phi \approx 380$ MeV. The factor 2 is from the fact that the chimera baryon $\psi\psi\phi$ includes two $\psi$'s.

For the chimera baryon $\phi\phi\phi$, we can see that it has the same tendency as chimera mesons $\phi^1\psi$ and chimera baryons $\psi\psi\phi$ in terms of $m_\phi$ and $M_\pi$ dependence from Figs. 6–8. The constituent scalar-quark/quark picture, $M_{\phi\phi\phi} \approx 2M_\phi + M_\phi$ for $M_\phi \approx 1.6$ GeV and $M_\pi \approx 400$ MeV, is satisfied. The magnitude of $m_\phi$-dependence of $M_{\phi\phi\phi}$ is about twice larger than that of chimera mesons, because the chimera baryon $\phi\phi\psi$ has two $\phi$'s. $m_\phi$-dependence is almost the same as that of chimera mesons.

The small $m_\phi$-dependence of chimera hadrons can be explained by the following simple theoretical consideration. As was already mentioned in Sec. IV, we find the relation among $M_{\phi\phi\phi}$, $m_\phi$, and $\Sigma_\phi$ as $M_{\phi\phi\phi} \approx m_\phi^2 + \Sigma_\phi$ in Eqs. (19) and (20), where the self-energy $\Sigma_\phi$ has only weak $m_\phi$-dependence and is almost constant. On the other hand, the mass of the chimera hadron including $n_\phi\phi$'s and $n_\phi\psi$'s, $M_{n_\phi\phi + n_\phi\psi}$, is approximately described by

$$M_{n_\phi\phi + n_\phi\psi} \approx n_\phi M_\phi + n_\phi M_\psi.$$  

FIG. 8. The mass of chimera baryons, $M_{\phi\phi\phi}$, plotted against pion mass squared $M_\pi^2$ in the unit of GeV$^2$. The notation, unit, and notices are same as those of Fig. 6.
Using Eqs. (21) and (23), we obtain for $|m^2_\phi| \ll \Sigma_\phi$ the relation between $M_{n_\phi n_\phi}$ and $m^2_\phi$ as

$$M_{n_\phi n_\phi} \approx (n_\phi \sqrt{\Sigma_\phi} + n_\phi M_\phi) + \frac{n_\phi}{2} \frac{m^2_\phi}{\sqrt{\Sigma_\phi}} \approx K m^2_\phi + (m_\phi\text{-independent part}) \quad (24)$$

up to the first order of the expansion by $m^2_\phi/\Sigma_\phi$. In our calculation range of $|m^2_\phi| \leq (0.33 \text{ GeV})^2$, $|m^2_\phi|$ is much smaller than $\Sigma_\phi \approx (1.5 \text{ GeV})^2$, i.e., $|m^2_\phi|/\Sigma_\phi \approx 0.048(\ll 1)$, and hence this expansion is expected to be rather good. The slope parameter $K$ is theoretically conjectured as $K = n_\phi/(2\sqrt{\Sigma_\phi})$. We show in Fig. 9 the chimera meson mass $M_{\phi^+\phi}$ and the chimera baryon mass, $M_{\psi\phi\phi}$ and $M_{\phi\phi\phi}$, plotted against the bare scalar-quark mass squared $m^2_\phi$ at the pion mass $M_\pi \approx 0.49$ GeV. In the figure, we observe the linear $m^2_\phi$-dependence for all the chimera hadrons. The slopes of these lines are 0.395 GeV$^{-1}$ for $\phi^+\psi$, 0.395 GeV$^{-1}$ for $\psi\psi\phi$, and 0.762 GeV$^{-1}$ for $\phi\phi\phi$ from the lattice data. On the other hand, the slope $K$ is $n_\phi/(2\sqrt{\Sigma_\phi})$ for the chimera hadron including $n_\phi\phi$'s from the theoretical conjecture of Eq. (24): the theoretical estimate of the slope $K$ is $0.333 \text{ GeV}^{-1}$ for $\phi^+\psi$, $0.333 \text{ GeV}^{-1}$ for $\psi\psi\phi$, and 0.666 GeV$^{-1}$ for $\phi\phi\phi$. The values of slopes from lattice data approximately agree with those from the theoretical estimation. Thus, $m^2_\phi$-dependence of the chimera hadron masses can be explained with Eq. (24), and the $m_\phi$-dependence is rather weak due to the large self-energy of scalar quarks, $\Sigma_\phi$.

Here, we also note the particular similarity between chimera mesons $\phi^+\psi$ and $\phi\phi\psi$-type chimera baryons in Figs. 6 and 8. To see this, we investigate the $M_\pi^2$-dependence of chimera mesons $\phi^+\psi$ and chimera baryons, $\psi\psi\phi$ and $\phi\phi\phi$. The relation between the bare quark mass $m_\phi$, the constituent quark mass $M_\phi$, and the self-energy for quarks, $\Sigma_\phi$, is described as

$$M_\phi \approx m_\phi + \Sigma_\phi. \quad (25)$$

The bare quark mass $m_\phi$ is proportional to the pion mass squared $M_\pi^2$, in the small $m_\phi$ region, i.e., near the chiral limit, from the Gell-Mann-Oakes-Renner relation, $f_\pi^2 M_\pi^2 \approx -2m_\phi\langle \bar{q}q \rangle$. i.e., $m_\phi \approx k M_\pi^2$ with $k = -f_\pi^2/(2\langle \bar{q}q \rangle)$. Inserting Eq. (25) into Eq. (24), the mass $M_{n_\phi n_\phi}$ of the chimera hadron including $n_\phi\phi$'s and $n_\phi\psi$'s is estimated in terms of $m^2_\phi$ and $M_\pi^2$ as

$$M_{n_\phi n_\phi}(m^2_\phi, M_\pi^2) \approx (n_\phi \sqrt{\Sigma_\phi} + n_\phi \Sigma_\phi) + \frac{n_\phi}{2} \frac{m^2_\phi}{\sqrt{\Sigma_\phi}} + n_\phi k M_\pi^2. \quad (26)$$

We investigate the mass difference,

![Fig. 9. Chimera meson mass $M_{\phi^+\psi}$, chimera baryon mass $M_{\psi\phi\phi}$, and chimera baryon mass $M_{\phi\phi\phi}$ plotted against bare scalar-quark mass squared $m^2_\phi$ in unit of GeV. The pion mass of the figure data is $M_\pi \approx 0.49$ GeV. Linear dependence of these masses for $m^2_\phi$ can be seen.](image-url)
for the chimera hadrons including \( n_\phi \) \( \phi \)'s and \( n_\psi \) \( \psi \)'s. Then, we expect the following relation near the chiral limit as

\[
\Delta M_{\phi+\phi} = \Delta M_{\phi'\phi} = \Delta M_{\phi\phi}/2 = kM_\pi^2.
\]

Figure 10 shows \( \Delta M_{\phi'\phi} \), \( \Delta M_{\phi\phi} \), and \( \Delta M_{\phi\phi}/2 \) plotted against \( M_\pi^2 \) at \( m_\phi = 0, 0.11, 0.22, \) and 0.33 GeV. We find a clear linear \( M_\pi^2 \)-dependence for these chimera hadrons. Since the four data with different values of \( m_\phi \) almost coincide at each case of chimera hadrons, there is almost no \( m_\phi \)-dependence for these mass differences, indicating that the quark in chimera hadrons is insensitive to the bare scalar-quark mass \( m_\phi \). We find the accurate coincidence between \( \Delta M_{\phi'\phi} \) and \( \Delta M_{\phi\phi} \) within several MeV, and some deviation between these two and \( \Delta M_{\phi\phi}/2 \). Therefore, we expect a similar structure between the chimera meson \( \phi'\psi \) and the chimera baryon \( \phi\phi\psi \), while the chimera baryon \( \psi\phi\psi \) is somewhat different from these two chimera hadrons.

These features can be understood by the following non-relativistic picture. Because of the large mass of the scalar quark, the wave function of \( \phi' \) in the chimera meson \( \phi'\psi \) is localized near the center of mass of the system, and the wave function of \( \psi \) distributes around the heavy anti-

\[
\Delta M_{\phi'\phi} = \Delta M_{\phi'\phi} = \Delta M_{\phi\phi}/2 = kM_\pi^2.
\]

FIG. 10. \( \Delta M_{\phi'\phi} = \Delta M_{\phi'\phi} = \Delta M_{\phi\phi}/2 = M_\phi^2 / (m_\phi^2 + M_\pi^2 - M_{\phi\phi}^2) = 0 \), \( \Delta M_{\phi\phi}/2 = (M_{\phi\phi}^2 / (m_\phi^2 + M_\pi^2 - M_{\phi\phi}^2) = 0) / 2 \), and \( \Delta M_{\phi\phi} = M_{\phi\phi}^2 / (m_\phi^2 + M_\pi^2 - M_{\phi\phi}^2) = 0 \) plotted against \( M_\pi^2 \) at \( m_\phi = 0, 0.11, 0.22, \) and 0.33 GeV. Different symbols correspond to the different types of the chimera hadrons (triangle: chimera mesons \( \phi'\psi \); circle: chimera baryons \( \phi\phi\psi \); square: chimera baryons \( \psi\phi\psi \)). The four data at \( m_\phi = 0, 0.11, 0.22, \) and 0.33 almost coincide at each case, indicating \( m_\phi \)-independence for these mass differences. The difference between \( \Delta M_{\phi'\phi} \) and \( \Delta M_{\phi\phi} \) is only several MeV.

scalar-quark as shown in Fig. 11(a). On the other hand, for chimera baryons \( \phi\phi\psi \), two \( \phi \)'s get close in the one-gluon-exchange Coulomb potential due to their heavy masses. Therefore, two \( \phi \)'s behave like a pointlike “discalar-quark.” As a result, the structure of chimera baryons \( \phi\phi\psi \) is similar to that of chimera mesons \( \phi'\psi \): the wave function of \( \phi\psi \) is localized near the center of mass, and that of \( \psi \) distributes around \( \phi\phi \) as shown in Fig. 11(b). The difference between these two systems is only the mass of the heavy object (\( M_\phi \) for \( \phi'\psi \) and 2\( M_\phi \) for \( \phi\phi\psi \)). The heavy-light system is mainly characterized by the light object, because the heavy object only gives the potential and the reduced mass in the system is almost the mass of the light object. We note that such a similarity between the chimera meson \( \phi'\psi \) and the chimera baryon \( \phi\phi\psi \) is originated from the large quantum correction of bare scalar-quark mass \( m_\phi \).

VI. CONCLUSION AND DISCUSSION

We have performed the first study for the light scalar-quarks \( \phi \) and their color-singlet hadronic states using quenched SU(3) lattice QCD in terms of their mass generation. We have investigated the scalar-quark bound states (scalar-quark hadrons): scalar-quark mesons \( \phi'\phi \) and scalar-quark baryons \( \phi\phi\phi \). We have also investigated the bound states of scalar-quarks and quarks, which we name “chimera hadrons”: chimera mesons \( \phi'\psi \) and chimera baryons, \( \psi\phi\psi \) and \( \phi\phi\psi \). For the lattice QCD calculation, we have adopted the standard plaquette action for the gluon sector, and the Wilson fermion action for the quark sector. We have presented the simplest local and gauge-invariant lattice action of scalar quarks. We have adopted \( \beta = 2N_c/g^2 = 5.70 \), which corresponds to the lattice spacing \( a \approx 0.18 \text{ fm} = (1.1 \text{ GeV})^{-1} \), and lattice size \( 16^3 \times 32 \) [spatial volume \( V = (2.9 \text{ fm})^3 \)]. For the bare scalar-quark mass, we have adopted \( m_\phi = 0.0, 0.11, 0.22, \) and 0.33 GeV, and for the bare quark mass, \( \kappa = 0.1650, 0.1625, \) and 0.1600. Fitting the temporal correlator
of each new-type hadron by a single exponential function, we have extracted the mass of the lowest state of the hadrons.

For the scalar-quark hadrons, we have found their large mass. The masses of scalar-quark mesons $\phi^+\phi$ and scalar-quark baryons $\phi\phi\phi$ at $m_\phi = 0$ are about 3 and 4.7 GeV, respectively. We have found the constituent scalar-quark picture, i.e., $M_{\phi^+\phi} \approx 2M_\phi$ and $M_{\phi\phi\phi} \approx 3M_\phi$, where $M_\phi$ is the constituent scalar-quark mass about 1.5 GeV. We have also found that, even in the case of $m_\phi^2 \leq 0$, the calculation can be performed for $m_\phi^2 \geq -(1.2 \text{ GeV})^2$. $m_\phi$-dependence of scalar-quark hadron masses squared is linear with respect to $m_\phi^2$ except for the large negative region of $m_\phi^2$. This is natural because the relation between the constituent scalar-quark mass $M_\phi$ and bare scalar-quark mass $M_\phi$ is written as $M_\phi^2 = m_\phi^2 + \Sigma_\phi$. For the chimera hadrons, we have also found their large masses: $M_{\phi^+\phi} \approx 1.9 \text{ GeV}$, $M_{\phi\phi\phi} \approx 2.2 \text{ GeV}$, and $M_{\phi\phi\phi} \approx 3.6 \text{ GeV}$, for $m_\phi = 0$ and $M_\pi = 0$. The constituent scalar-quark/quark picture is also satisfied, i.e., $M_{\phi\phi\phi+\phi\phi\phi} \approx mM_\phi + nM_\phi^2$, where constituent scalar-quark mass $M_\phi = 1.5$–1.6 GeV and constituent quark mass $M_\phi = 400 \text{ MeV}$. $m_\phi$-dependence of chimera-hadron masses is weak and the bare quark mass $m_\phi$ seems to govern their systems in our calculated range of $m_\phi$ and $M_\phi$. The small $m_\phi$-dependence of chimera hadrons can be explained by a simple theoretical consideration. Because of the large mass generation of $\phi$, there occurs similarity of the structure between chimera mesons $\phi^+\phi$ and chimera baryons $\phi\phi\phi$.

The large mass generation of the scalar-quark $\phi$ reflects the general argument of large quantum corrections for scalar particles. As another famous example, the Higgs scalar field suffers from large radiative corrections in the grand unified theory (GUT), and to realize the low-lying mass of the Higgs scalar inevitably requires “fine-tuning” related to the gauge hierarchy problem [24,34]. In fact, while the typical energy scale of the electroweak unification is about $O(10^2 \text{ GeV})$ and the Higgs scalar mass is to be also $O(10^2 \text{ GeV})$, the GUT scale, i.e., the typical energy scale of the electroweak and strong unification is conjectured to be extremely large as $E_{\text{GUT}} \sim 10^{15}$–$10^{16} \text{ GeV}$. In the simple GUT scenario, the standard model is regarded as an effective theory applicable up to the GUT scale $E_{\text{GUT}}$, which can be identified as the cutoff scale of the standard model as $\Lambda \sim E_{\text{GUT}}$. For the self-energy of the Higgs scalar, $\Sigma_H$, there appears a large quantum correction including second-order divergence as $\Sigma_H \sim \Lambda^2$, with the cutoff parameter $\Lambda$. This is because scalar particles do not have symmetry restriction like the chiral symmetry for light fermions and the gauge symmetry for vector gauge bosons. Therefore, it is natural that the Higgs scalar receives a huge quantum correction of order $E_{\text{GUT}}$, and, in order to realize the low-lying physical Higgs mass of order $10^2 \text{ GeV}$, an extreme fine-tuning is necessary for the bare mass of the Higgs scalar. This is the problem of fine-tuning for the Higgs scalar. In lattice QCD, the self-energy of scalar-quarks $\Sigma_\phi$ also receives a large quantum correction including the second-order divergence as $\Sigma_\phi \sim \Lambda^2$, similar to the Higgs scalar. Since the constituent mass $M_\phi$ of the scalar quark satisfies the relation of $M_\phi^2 \approx m_\phi^2 + \Sigma_\phi$ with the bare mass $m_\phi$ from a general argument of the scalar field, the constituent scalar-quark mass $M_\phi$ takes a large value even at $m_\phi = 0$ as $M_\phi \approx \Sigma^{1/2} \sim \Lambda$. Note here that the lattice QCD can be regarded as a cutoff theory with the cutoff about the lattice spacing as $\Lambda \sim a^{-1}$. Actually, the quantum correction to the scalar-quark mass is found to be about 1.5 GeV in this lattice study, which is approximately the same order of the cutoff scale $a^{-1} \approx 1 \text{ GeV}$. (From a finer lattice calculation at $\beta = 6.10$ in the Appendix, the large quantum correction for the scalar-quark mass is conjectured to be proportional to the lattice cutoff scale.) In this way, the large quantum correction to the scalar quarks is naturally explained.

Here, we comment on the continuum limit of the system including scalar quarks. As was already shown, the quantum correction for the scalar-quark mass is quite large and becomes infinite in the continuum limit, which is indicated by a finer lattice calculation at $\beta = 6.10$ in the Appendix. To take the continuum limit with keeping the (constituent) scalar-quark mass finite, one has to tune the bare scalar-quark mass so as to make the related physical quantities like scalar-quark hadron masses finite, during the decrease of lattice spacing. In the fine-tuned case, the bare scalar-quark mass squared becomes negative infinity so as to cancel the infinitely large quantum correction. In this way, the continuum limit where the (constituent) scalar-quark mass is finite can be achieved by tuning the bare mass of scalar quarks in principle. However, without such a fine-tuning, the scalar-quark systems are conjectured to be infinitely massive and to lose the physical relevance in the continuum limit, because of the large quantum correction for the scalar-quark mass. This situation is rather different from that of fermion systems in QCD, where such a fine-tuning of the bare mass is not needed.

To include dynamical scalar quarks is one of the possible future works. Since the scalar quarks are described to be Grassmann-even variables like real numbers, we can set the scalar-field variable $\phi(x)$ directly on the lattice using real numbers, and perform the actual Monte Carlo calculation including dynamical scalar quark using the standard heat-bath algorithm. This point is essentially different from the case of fermions: since fermions are described by Grassmann-odd variables, to include the dynamical effect of fermions in the Monte Carlo calculation, a huge calculation of fermionic determinant is needed. In contrast, to include the dynamical scalar quarks, we need not perform the huge calculation of functional determinant of the scalar field. However, the dynamical effect of such a “heavy”
In terms of the diquark picture, we find that the pointlike diquarks interacting with gauge fields have large mass about 1.5 GeV at the cutoff $a^{-1} \approx 1$ GeV which is about the hadronic scale. The diquark mass of about 1.5 GeV is too heavy to use in effective models of hadrons. Therefore, the lattice result indicates that the simple modeling which treats the diquark as a local scalar field at the scale of $a^{-1} \sim 1$ GeV in QCD is rather dangerous. If we treat the diquark as a pointlike object, we must do the subtle tuning of the diquark model, and the model cannot be a simple one like QCD.

In this way, even without chiral symmetry breaking, large dynamical mass generation occurs for the scalar-quark systems as scalar-quark/chimera hadrons. Together with the large glueball mass ($>1.5$ GeV) and large difference ($\sim 400$ MeV) between current and constituent charm-quark masses, this type of mass generation would generally occur in the strong interaction, and therefore we conjecture that all colored particles generally acquire a large effective mass due to dressed gluon effects as shown in Fig. 12.

Our lattice QCD calculations have been performed on NEC-SX5 and NEC-SX8 at Osaka University.

**APPENDIX: SCALAR-QUARK MESON MASS AT $\beta = 6.10$**

In this Appendix, regarding the scalar quark as a pointlike object, we investigate the scalar-quark meson mass $M_{\phi}^2$ with a finer lattice at $\beta = 6.10$ to check the approximate relation that the large self-energy for scalar quarks is almost proportional to the cutoff scale as $\sqrt{\Sigma_\phi} \propto a^{-1}$. The scalar quark is expected to be small in the actual calculation, considering the large constituent scalar-quark mass generation as $M_{\phi} \approx 1.5-1.6$ GeV.

In terms of the diquark picture, we find that the pointlike diquarks interacting with gauge fields have large mass about 1.5 GeV at the cutoff $a^{-1} \approx 1$ GeV which is about the hadronic scale. The diquark mass of about 1.5 GeV is too heavy to use in effective models of hadrons. Therefore, the lattice result indicates that the simple modeling which treats the diquark as a local scalar field at the scale of $a^{-1} \sim 1$ GeV in QCD is rather dangerous. If we treat the diquark as a pointlike object, we must do the subtle tuning of the diquark model, and the model cannot be a simple one like QCD.

In this way, even without chiral symmetry breaking, large dynamical mass generation occurs for the scalar-quark systems as scalar-quark/chimera hadrons. Together with the large glueball mass ($>1.5$ GeV) and large difference ($\sim 400$ MeV) between current and constituent charm-quark masses, this type of mass generation would generally occur in the strong interaction, and therefore we conjecture that all colored particles generally acquire a large effective mass due to dressed gluon effects as shown in Fig. 12.

The lattice result for the scalar-quark mass at $\beta = 6.10$ is summarized in Table VII. We show in Fig. 13 the relation between the scalar-quark mass $M_{\phi}^2$ and the bare scalar-quark mass $m_{\phi}$ at $\beta = 6.10$. The $m_{\phi}$-dependence of $M_{\phi}^2$ is found to be approximately linear. Similar to the case at $\beta = 5.70$, this behavior can be explained with the constituent scalar-quark picture of $M_{\phi}^2 = 2M_{\phi} + \Sigma_{\phi}$, with $\Sigma_{\phi}$ being almost $m_{\phi}$-independent. At $\beta = 6.10$, the scalar-quark meson mass $M_{\phi}^2$ at $m_{\phi} = 0$ is found to be about 5.5 GeV, and thus the self-energy for scalar quarks is estimated as $\sqrt{\Sigma_{\phi}} \approx 2.8$ GeV, which is about twice larger than that at $\beta = 5.70$.

We compare the lattice result at $\beta = 6.10$ with that at $\beta = 5.70$ for the scalar-quark meson mass $M_{\phi}^2$ in the case of $m_{\phi} = 0$, because of $M_{\phi}^2 = 2\sqrt{\Sigma_{\phi}}$ in the constituent picture. For $m_{\phi} = 0$, we find the approximate scaling relation as

$$
\frac{(M_{\phi}^2 a)|_{\beta = 6.10}}{(M_{\phi}^2 a)|_{\beta = 5.70}} \approx 0.9, 
$$

which indicates a large quantum correction as $\sqrt{\Sigma_{\phi}} \propto a^{-1}$ mentioned in Sec. VI. In this way, if one considers the pointlike scalar quark, its self-energy $\Sigma_{\phi}$ diverges in the continuum limit, and hence, to eliminate the divergence depending on the cutoff, one needs a fine-tuning of the bare scalar-quark mass $m_{\phi}$. For the argument of the diquark, however, there appears a natural cutoff corresponding to its intrinsic size as a composite object.
FIG. 13. The lattice results for scalar-quark mesons $\phi^+\phi$ at $\beta = 6.10$: (a) The scalar-quark meson mass $M_{\phi^+\phi}$ plotted against the bare scalar-quark mass $m_\phi^\text{bare}$ and (b) $M_{\phi^+\phi}^2$ against $m_\phi$. A large mass of scalar-quark mesons about 5.5 GeV even at $m_\phi = 0$ and approximate linear $m_\phi^2$-dependence of $M_{\phi^+\phi}^2$ are observed.
