To overcome these difficulties, two independent laboratories constructed IL-15 reporter mice by introducing BAC transgenes harboring genes encoding fluorescent reporters controlled by the IL-15 promoter (13, 14). By using these mice, they detected significant fluorescence signals in CD8\textsuperscript{+} conventional DCs (cDCs) and macrophages, expression augmented by vesicular stomatitis virus stimulation. However, reporter-expressing cells have not been reported in stromal cell populations. Such an inability to detect IL-15–expressing cells could be explained if BAC transgenes lacked regulatory elements required for IL-15 expression in stromal cells. Therefore, the distribution of IL-15–expressing cells is not completely characterized.

Here, to characterize the IL-15–expressing cells in vivo, we established a unique reporter mouse line, in which an enhanced CFP cDNA was inserted into the endogenous IL-15 locus. By using the IL-15–CFP knock-in mice, we revealed IL-15–expressing stromal cells showing a distinct distribution in primary and secondary lymphoid organs. Moreover, we demonstrated age-dependent augmentation and LPS-induced enhancement of IL-15 expression in some stromal cells. Thus, we have identified a unique category of IL-15–expressing cells by using an IL-15–CFP knock-in mouse that serves as a sensitive tool to dissect IL-15 niche in vivo.

Taken together with previous observations of IL-7–GFP knock-in mice, we suggest that IL-7 and IL-15 are expressed in the immune microenvironment in distinct but occasionally overlapping patterns.

Results

Generation of IL-15–CFP Knock-in Mice. To determine the distribution of IL-15–producing cells in vivo, we generated IL-15–CFP

Significance

IL-15 is a cytokine critical for development and maintenance of T lymphoid cells. However, the identity and distribution of IL-15–expressing cells in lymphoid organs are not well understood. The present study reveals, by using IL-15–CFP knock-in mice that IL-15 was expressed in subsets of thymic epithelial cells, bone marrow stromal cells, lymph node stromal cells, and blood endothelial cells, a unique perspective of IL-15 niche in immune microenvironment. Taken together with our previous observation on IL-7–producing cells, this study suggests that some stromal cells express IL-7 and IL-15 differentially. Thus, the immune microenvironment appears to be consisted of functionally distinct subsets of stromal cells, expressing different cytokines.

knock-in mice. CFP cDNA and a neomycin resistance cassette were inserted at the ATG codon of the third IL-15 exon by homologous recombination (Fig. S1). The neomycin cassette was then removed by Cre recombinase. We analyzed IL-15–CFP heterozygotes in all experiments. IL-15–CFP mice showed normal development of lymphoid organs.

**IL-15 Is Highly Expressed in Thymic Medulla.** Previous reports demonstrated significantly reduced numbers of thymic NK and NKT cells in IL-15 KO mice, although the source of IL-15 had not been identified (5). To detect an IL-15 signal directly, we performed multiphoton microscopy by using thymus freshly excised from IL-15–CFP mice and littermate controls. CFP signals were clearly detected in thymus, and many were clustered in distinct areas (Fig. S2A).

To identify IL-15–expressing cells in thymus, we performed immunohistochemistry by using an anti-GFP antibody combined with staining of cortical thymic epithelial cells (TECs; cTECs) and medullary TECs (mTECs) with anti-Ly51 and anti-EpCAM antibodies, respectively. Surprisingly, IL-15–expressing cells were predominantly localized in the thymic medulla and displayed EpCAM staining, whereas a few were scattered in corticomedullary junction and coexpressed Ly51 marker (Fig. L4). Furthermore, many mTECs expressing IL-15 also expressed high levels of MHC class II (MHC-II<sup>high</sup>) in thymic medulla (Fig. 1B). We also stained blood endothelial cells (BECs) and pericytes with anti-CD31 and anti-PDGFR<sub>β</sub> antibodies, respectively, and found that most BECs and some pericytes expressed IL-15, primarily in the thymic medulla (Fig. 1C). To discriminate between hematopoietic and nonhematopoietic cells, we stained DCs and macrophages with anti-CD11c and anti-CD11b antibodies as well as anti-CD31 and anti-GFP antibodies. In contrast to IL-15–expressing CD31<sup>+</sup> BECs, DCs, and macrophages in thymus lacked IL-15 expression (Fig. S2B). These results suggest that MHC-II<sup>high</sup> mTECs were the major source of IL-15 in the thymus.

**IL-15 Expression in Bone Marrow Stromal Cells.** IL-15 translation functions in development and homeostasis of NK, NKT, and memory CD8<sup>T</sup> cells in bone marrow (15, 16). To monitor IL-15 signals, we carried out multiphoton microscopy with calvaria of IL-15–CFP mice and littermate controls in vivo. We found that some IL-15–expressing cells were distributed around small blood vessels in bone marrow (Fig. S2C). To further characterize IL-15–expressing cells, we stained cryosections of bone marrow with anti–VCAM-1 (for bone marrow stromal cells) and anti-GFP antibodies. IL-15–expressing cells were scattered throughout the entire bone marrow (Fig. 1D). Most IL-15 signals colocalized with VCAM-1<sup>+</sup> stromal cells. Furthermore, numerous VCAM-1<sup>+</sup> stromal cells exhibiting an extended triangular morphology and located adjacent to blood vessels expressed high levels of IL-15 (Fig. 1D, Left). We also performed multiphoton microscopy with calvaria of IL-15–CFP/IL-7<sup>+</sup> CFP double knock-in mice in vivo. We found that most IL-15–expressing cells overlapped with IL-7–expressing cells, whereas some IL-7–expressing cells lacked IL-15 expression in bone marrow (Fig. S2D).

**Differential IL-15 Expression in Thymic Stromal Populations.** We next characterized the nature of IL-15–expressing cells in thymus by flow cytometry using anti-GFP antibody. We carried out flow cytometry of CD45<sup>−</sup>Ter119<sup>+</sup> thymic stromal cells. TECs were separated into three subsets with anti-Ly51, anti-EpCAM, and anti–MHC-II antibodies (Fig. 2A). MHC-II<sup>high</sup> mTECs expressed high IL-15 levels, whereas a small fraction of MHC-II<sup>low</sup> mTECs expressed anti-CD31<sup>+</sup> and anti-PDGFR<sub>β</sub> antibodies, respectively, and found that most BECs and some pericytes expressed IL-15, primarily in the thymic medulla (Fig. 1C). To discriminate between hematopoietic and nonhematopoietic cells, we stained DCs and macrophages with anti-CD11c and anti-CD11b antibodies as well as anti-CD31 and anti-GFP antibodies. In contrast to IL-15–expressing CD31<sup>+</sup> BECs, DCs, and macrophages in thymus lacked IL-15 expression (Fig. S2B). These results suggest that MHC-II<sup>high</sup> mTECs were the major source of IL-15 in the thymus.

**IL-15 Is Highly Expressed in a Fraction of Mesenchymal Stromal Cells in Bone Marrow.** The major source of IL-15 in bone marrow is reportedly a distinctive stromal cell population known as CXCL12-abundant reticular (CAR) cells (17). We separated CD45<sup>−</sup>Ter119<sup>+</sup> bone marrow stromal cells into CD31<sup>+</sup>Sca-1<sup>+</sup> BECs, CD31<sup>−</sup>Sca-1<sup>+</sup> cells, and VCAM-1<sup>+</sup>PDGFR<sub>β</sub><sup>high</sup>CD31<sup>−</sup>Sca-1<sup>+</sup> stromal cells (Fig. 2F), and assessed CFP expression. More than 60% of VCAM-1<sup>+</sup>PDGFR<sub>β</sub><sup>high</sup>CD31<sup>−</sup>Sca-1<sup>+</sup> CAR cells expressed high IL-15 levels, whereas a subset of CAR cells lacked IL-15 expression. In addition, fewer than 10% of VCAM-1<sup>+</sup>PDGFR<sub>β</sub><sup>high</sup>CD31<sup>−</sup>Sca-1<sup>+</sup> stromal cells expressed low levels of IL-15, and BECs and CD31<sup>−</sup>Sca-1<sup>+</sup> stromal cells in bone marrow completely lacked IL-15 expression (Fig. 2G). IL-15 and CXCL12 transcripts were analyzed in BECs and in CFP<sup>+</sup> and CFP<sup>−</sup> CAR cells sorted from IL-15–CFP mice using quantitative RT-PCR. IL-15 transcript levels were significantly greater in the CFP<sup>+</sup> fraction of CAR cells than in CFP<sup>−</sup> CAR cells and BECs (Fig. 2H). Strikingly, CXCL12 transcripts were highly expressed in CFP<sup>+</sup> and CFP<sup>−</sup> CAR cells compared with BECs (Fig. 2I). These results indicate that IL-15 is expressed primarily in a subset of CAR cells.

**IL-15 Is Expressed in the T-Cell Zone and Medulla of Lymph Nodes.** Apart from its role in primary lymphoid organs, IL-15 is also critical for homeostasis of T, NK, and NKT cells in the periphery (4, 5). Thus, we examined peripheral lymph nodes by immunohistochemistry with anti-gp38 [for fibroblastic reticular cells (FRCs)], anti-CD11c

---

**Fig. 1.** Distribution of IL-15–expressing cells in primary lymphoid organs. Immunohistochemical analysis of thymus (A–C) and bone marrow (D) of 6- to 10-wk-old IL-15–CFP knock-in mice (IL-15<sup>Cre</sup>+) and control WT littermates. CFP signals were detected with anti-GFP antibody. (A and B) mTECs and cTECs were stained with anti-EpCAM (red) and anti-Ly51 (blue) antibodies, respectively. MHC-II<sup>high</sup> mTECs (green) in medulla display the mTEC marker and these double stained (red and green overlap) cells appear yellow, whereas a few cTECs at the corticomedullary junction also express IL-15 (A, arrowheads). CFP<sup>+</sup> mTECs were coexpressed with anti–MHC-II antibody, and these triple-stained cells (red, green, and blue overlap) appear white (B, arrowheads), C, cortex; M, medulla. (C) BECs and pericytes were stained with anti-CD31 (green) and anti-PDGFR<sub>β</sub> (light blue) antibodies, respectively. BECs and pericytes (arrows) coexpressed with CFP<sup>+</sup> cells (red). These double stained cells appear yellow and white, respectively. (D) VCAM-1<sup>+</sup> stromal cells (blue), which are primarily adjacent to blood vessels (arrows), express high levels of CFP (red). Data represent three independent experiments with similar results. (Scale bar, 100 μm.)
(for DCs), and anti-CD3 (for T cells) antibodies, as well as using an anti-GFP antibody. Interestingly, IL-15–expressing cells were predominant in the T-cell zone and medulla but absent from B-cell–rich follicles in axillary, cervical, and inguinal lymph nodes (Fig. 3A and B). In contrast, only a few IL-15–expressing cells were present in the T-cell zone of mesenteric lymph nodes (Fig. 3B).

As stromal cells of the lymph node can be divided into four fractions with anti-gp38 and anti-CD31 antibodies (18, 19), we carried out flow cytometry of CD45<sup>−</sup>Ter119<sup>−</sup> lymph node stromal cells and divided them into gp38<sup>+</sup>CD31<sup>+</sup> FRCs, gp38<sup>+</sup>CD31<sup>−</sup> lymphatic endothelial cells (LECs), gp38<sup>−</sup>CD31<sup>+</sup> BECs, and double-negative stromal cells (DNSCs) (Fig. 3C). IL-15 was expressed in 40–50% of FRCs but completely absent from LECs. Importantly, more than 80% of BECs expressed significantly high levels of IL-15 in peripheral lymph nodes (Fig. 3D, Upper). In contrast, whereas BECs expressed high levels of IL-15, only a limited number of FRCs expressed very low levels of IL-15 in mesenteric lymph nodes (Fig. 3D, Lower). Moreover, some DNSCs in the T-cell zone expressed IL-15 in peripheral lymph nodes (Fig. 3D, Upper).

We next performed immunohistochemistry with sections of lymph node tissue by using anti-gp38 and anti-CD31 antibodies. Consistent with the flow cytometry results, BECs and FRCs but not LECs expressed IL-15 in lymph nodes (Fig. 3E). All high endothelial venules (HEVs) also expressed high IL-15 levels, whereas only approximately half of non-HEV BECs expressed IL-15 (Fig. 3F). Some DNSCs in T-cell zones expressed high IL-15 levels (Fig. 3G). We also confirmed IL-15 expression in some hematopoietic subsets such as DCs and macrophages by staining with anti-CD31 and anti-CD11c or anti-CD11b antibodies as well as anti-GFP antibody. We found that some DCs and macrophages adjacent to IL-15–expressing stromal cells were CFP<sup>+</sup> in lymph nodes (Fig. 3A and B). Additionally, the frequency of DCs and macrophages in all IL-15–expressing cells in T-cell zone was less than 10%. Overall, these results demonstrate that a variety of stromal cells in the T-cell zone and medulla express IL-15 in lymph nodes and that all HEVs show significant IL-15 expression.

**Age-Dependent IL-15 Expression in Splenic Stromal Cells.** To investigate IL-15–expressing cells in spleen, we analyzed sections of spleen tissue using anti–VCAM-1 (for splenic stromal cells) and anti-CD3 antibodies as well as anti-GFP antibody. CFP signals were very weak in young (1 mo old) mice but nonetheless detectable in VCAM-1<sup>+</sup> stromal cells within the T-cell zone and red pulp (Fig. 4A). Consistent with previous reports that IL-15 is expressed by DCs in spleen, we found that CD8<sup>+</sup> cDCs were the major source of IL-15 in the DC fraction, whereas plasmacytoid DCs completely lacked IL-15 expression (Fig. 3C and D).

Because the number of NKT and CD8 T cells increases as mice age (20–22), we asked whether IL-15 expression in spleen also changes with aging. We found that IL-15 expression increased in aging (10 mo old) mice when compared with young mice (Fig. 4A). To characterize IL-15–expressing cells in aging spleen, we carried
out flow cytometry of CD45<sup>Ter119</sup> spleen stromal cells with anti–VCAM-1 and anti–CD31 antibodies (Fig. 4B). We observed IL-15 expression in VCAM-1<sup>−CD31</sup> stromal cells, and the number of CFP<sup>+</sup> stromal cells as well as CFP levels increased with age, whereas BECs did not express IL-15 at any time point (Fig. 4C and D). In contrast, IL-15 expression remained unchanged in stromal cell populations of aging lymph nodes (Fig. S4). These results suggest that IL-15 expression in splenic stromal cells is up-regulated in an age-dependent manner.

**Endothelial Cells in the Lamina Propria of the Small Intestine Strongly Express IL-15.** Several studies indicate that IL-15 produced by intestinal epithelial cells (IECs) supports maintenance of IELs in the small intestine (3, 23). Therefore, we analyzed small intestine tissue sections by immunohistochemistry with anti-EpCAM and anti-CD31 antibodies. Although detection of IL-15 mRNA in IECs has been reported, we observed extremely weak CFP signals only in a few epithelial cells. In contrast, we found some CFP<sup>+</sup> cells in lamina propria, and many were costained with anti-CD31 antibody (Fig. 4E). Thus, endothelial cells in the lamina propria may express higher IL-15 than IECs in small intestine.

**IL-15 Expression Increases Following LPS-induced Inflammation.** IL-15 plays a regulatory role in DCs in inflammation induced by LPS stimulation (7, 24). Thus, we analyzed IL-15 expression in DCs after LPS stimulation. IL-15 expression was slightly up-regulated in cDCs after stimulation (Fig. S5). To analyze IL-15–expressing stromal cells under inflammatory conditions, we injected IL-15–CFP knock-in mice with LPS and assessed potential changes in IL-15 expression 3 d later. In lymph nodes, the number of IL-15–expressing cells significantly increased (Fig. 5A). Surprisingly, induction of IL-15 expression was seen in gp38<sup>−CD31</sup> ELCs after LPS stimulation (Fig. 5A). Furthermore, we gated out hematopoietic cells with anti-CD45, anti-CD11c, and anti-CD11b antibodies by flow cytometry (Fig. S6), and evaluated the alteration of IL-15 expression in stromal cell subsets. In lymph nodes, the level of IL-15 expression by BECs significantly increased, and the proportion of IL-15<sup>high</sup> BEGs also increased by twofold. IL-15 expression in FRCs and DNSCs was unchanged after LPS administration (Fig. S5 B and C). In spleen, VCAM-1<sup>−CD31</sup> stromal cells expressed slightly higher IL-15 after stimulation. Notably, IL-15 was slightly induced in BECs by LPS stimulation (Fig. 5D and E). Overall, these results demonstrate that IL-15 expression in BECs and LECs of peripheral lymphoid organs significantly increases in the presence of LPS-induced inflammation.

**IL-15 Expression in Other Organs.** As IL-15 mRNA was detected in various organs such as lung, liver, kidney, heart, and skeletal muscle (1, 6), we performed immunohistochemistry of these organs in IL-15–CFP knock-in mice. We did not detect CFP signals in lung, liver, kidney, and skeletal muscle at steady state. However, we found that endocardium of heart expressed IL-15 (Fig. S7 A and C). Furthermore, we observed that liver macrophages expressed high levels of IL-15 after LPS stimulation (Fig. S7 B and C).

**Discussion**

The cytokine IL-15 plays critical roles in development, maintenance, and response of naive CD8 T cells, memory T cells, NK cells, NKT cells, and IELs. Although IL-15 expression by DCs has been reported, the distribution of IL-15–expressing cells in the stromal cell fraction remains relatively uncharacterized in part because of low protein expression. Recently, others constructed two BAC transgenic mouse lines to track IL-15–expressing cells (13, 14). However, in those mice, detection of IL-15–expressing cells was limited to hematopoietic subsets, possibly because the BAC constructs lack regulatory elements necessary for stromal cell IL-15 expression. We constructed an IL-15–CFP knock-in mouse and observed a variety of IL-15–expressing cells in lymphoid organs, suggesting that IL-15 expression is regulated differently between lymphoid and stromal cells.

MHC-II<sup>high</sup> mTECs may be the site for expansion of CD8 T cells and NKT cells in the thymus. IL-7 and other γε cytokines reportedly play a role in their expansion (25, 26). We found that MHC-II<sup>high</sup> mTECs produce high levels of IL-15. As IL-15 is a key regulator of development and homeostasis of CD8 T and NKT cells in thymus, the difference in IL-15 expression we observed between medulla and cortex suggests that a distinct IL-15 niche for CD8 T and NKT cells exists in thymic medulla. In that tissue, MHC-II<sup>high</sup> mTECs may provide a site for negative selection and maintenance of CD8 T and NKT cells.

CAR cells are the major source of IL-15 in bone marrow. We observed IL-15–expressing cells scattered in the entire bone marrow, many of them VCAM-1<sup>−PDGF</sup>FR<sup>−</sup>CD31<sup>−CD45Rc</sup> CAR cells. These results are consistent with a report that CAR cells express high levels of IL-15 mRNA (27) and suggest that IL-15–expressing cells support development and homeostasis of memory T, NK, and NKT cells. Interestingly, we identified IL-15<sup>+</sup> and IL-15<sup>+</sup> subsets of CAR cells.

IL-15 is critical for proliferation and maintenance of memory T cells, NK cells, NKT cells, and IELs. In lymph nodes, IL-15–expressing cells were localized in the T-cell zone and medulla. We found that some FRCs and DNSCs express IL-15. These stromal cells may function in homeostasis of memory T and NKT

---

**Fig. 4.** Characterization of IL-15–expressing cells in spleen and small intestine. CFP expression in spleen and small intestine of IL-15–CFP knock-in mice (IL-15<sup>CFP<sup>+</sup></sup>) and control WT littermates. CFP signals were detected with an anti-CFP antibody. (A) CFP<sup>+</sup> cells in spleen. Stromal cells and T cells were stained with anti-VCAM-1 and anti-CD31 antibodies, respectively. CFP<sup>+</sup> stromal cells (red and green overlap) appear yellow. (B and C) Age-dependent IL-15 expression in splenic stromal cells. Spleen cells from IL-15<sup>−</sup>CFP knock-in mice and control WT littermates were stained with anti-CD45, anti-VCAM-1, and anti-CD31 antibodies. BEC represents CD31<sup>−VCAM-1<sup>−</sup></sup> cells. (D) Percentages of CFP<sup>+</sup> cells in stromal cells and BECs of IL-15<sup>−</sup>CFP knock-in spleen. Values are the mean ± SEM from three independent experiments. *P < 0.01. (E) IECs and BECs were stained with anti-EpCAM and anti-CD31 antibodies. CFP<sup>+</sup> IECs (red and green overlap) appear yellow and magenta, respectively. BECs express high levels of IL-15 (arrowheads), whereas IECs express low levels of IL-15. P, Peyer patch; V, villi. (Scale bar, 100 μm.)
cells. One question to be addressed in future studies is whether IL-15--expressing FRCs and DNCSs have equivalent functions. In spleen, we identified IL-15--expressing VCAM-1+CD31+ stromal cells in the T-cell zone and red pulp. Interestingly, IL-15 expression by splenic stromal cells increased with age. The numbers of memory phenotype CD8 T and NKT cells reportedly increase in the aging spleen (20, 21). Therefore, IL-15--expressing stromal cells may serve as a splenic microenvironment supporting expansion of memory CD8 T and NKT cells.

BECs express IL-15 at high levels. We showed that BECs in thymus, lymph nodes, and Peyer patches express IL-15 at high levels. Remarkably, HEVs in lymph nodes express high IL-15 levels. IL-15 is reportedly important for interaction of T cells with BECs in vitro (28, 29). Our results suggest that IL-15 produced by BECs may function in adhesion and migration of lymphocytes in lymphoid organs.

Inflammation induces IL-15 in multiple cell types. LPS and inflammatory cytokines induce IL-15 in DCs (7). In this study, we showed that LPS also induces IL-15 expression in the stromal cell fraction. LPS-induced inflammation greatly increased IL-15 expression in BECs and LECs, whereas expression in other stromal cells was only slightly increased or unchanged. These results are consistent with reports that TLR4 is expressed in BECs and LECs (30, 31). IL-15 reportedly induces hyaluronate, which functions in lymphocyte rolling in blood vessels (28). Thus, autocrine secretion of IL-15 by BECs might induce hyaluronate and enhance extravasation of T cells and DCs in inflammation. Moreover, because DCs express IL-15Rα and help lymphocytes enter into lymph nodes through HEVs (32, 33), IL-15 produced by BECs and LECs might activate DCs in inflammation. Thus, IL-15 induction by BECs and LECs may alter lymphocyte migration in inflammation.

IL-7 and IL-15 are differentially expressed in some lymphoid organs (Table S1). We previously reported the distribution of IL-7--producing cells by using IL-7--GFP knock-in mice (34). In thymus, IL-15 is highly expressed in MHC-IIhi mTECs, whereas IL-7 is broadly expressed in cTECs and mTECs. Additionally, BECs in thymus expressed IL-15 but not IL-7. In bone marrow, IL-15 and IL-7 are expressed by VCAM-1+CD31+ stromal cells, and especially IL-15 is mainly expressed in a subset of VCAM-1+PDGFRβ+CD31+Sca-1+ CAR cells. However, IL-15 is not expressed in VCAM-1+CD31+ stromal cells and PDGFRα+Sca-1+ stromal cells, including mesenchymal stem cells and endothelial cells (35, 36), which express high levels of IL-7. Because most IL-15--expressing cells were contained in IL-7--expressing cell population in bone marrow of IL-15--CFP/IL-7--GFP double knock-in mice, some CAR cells seem to express IL-7. IL-15 is expressed in BECs, whereas IL-7 is expressed in LECs of lymph nodes and the intestinal lamina propria. Although FRCs express both IL-7 and IL-15 in lymph nodes, it is not clear whether IL-7-- and IL-15--producing cells overlap or constitute different populations because of undetectable levels of direct CFP and GFP fluorescence in secondary lymphoid organs of IL-15--CFP/IL-7--GFP double knock-in mice. Differential expression of IL-7 and IL-15 suggests that the immune microenvironment is organized, at least in part, as a mosaic of different cytokine-producing stromal populations, an arrangement that may facilitate efficient maintenance and responsiveness of lymphoid cells.

In conclusion, we successfully identified and characterized IL-15--expressing cells in primary and secondary lymphoid organs by using IL-15--CFP knock-in mice. Our study provides a perspective of the IL-15 niche in the immune microenvironment and will encourage analysis of the local functions of IL-15 produced by stromal cells in various lymphoid organs. Our study also indicates that IL-7 and IL-15 are differentially expressed by stromal cells and suggests a classification of functionally different stromal cell subsets.

Materials and Methods

Mice. Generation of IL-15--CFP knock-in mice is described in SI Materials and Methods. IL-7--GFP knock-in mice were reported previously (34). All mice were maintained under specific pathogen-free conditions in the Experimental Research Center for Infectious Diseases in the Institute for Virus Research, Kyoto University. All mouse protocols were approved by the animal research committee at the Institute for Virus Research, Kyoto University.

Isolation of Stromal Cells. Tissues were dissected into small pieces and incubated in 1 mL of RPMI medium 1640 mixture containing 1.25 mg/mL collagenase D (Roche), 0.8 mg/mL Dispase (Roche), and 0.1 mg/mL DNase (Roche) at 37 °C for 45 min with constant shaking. In the case of lymph nodes and spleen, the mixture also contained 0.2 mg/mL collagenase P (Roche). The cell suspension was gently passed twice through a 24-gauge needle and washed with PBS solution containing 0.5% BSA and 2 mM EDTA (i.e., MACS buffer). Hematopoietic cells were depleted with anti-CD45, anti-CD11c, and anti-CD11b antibodies. The percentages of CFP+CD45, CD11c+ and CD11b+ cells were shown in B. Values are the mean ± SEM from three independent experiments. **P < 0.01, NS, not significant.

Flow Cytometry. Cells were stained with fluorescent dye- or biotin-conjugated antibodies described in SI Materials and Methods. Hematopoietic cells were gated out with anti-CD45 and Ter119 antibodies. Intracellular staining was performed using Fix & Perm Cell Fixation and Permeabilization reagents (Invitrogen). An anti-GFP antibody (Invitrogen) with cross-reactivity to CFP was used to detect CFP. Stained cells were acquired with a FACS Canto II flow cytometer (BD Biosciences) and analyzed by using FlowJo software (TreeStar). Cell sorting was performed by using a FACS Aria II cell sorter (BD Biosciences).
**Immunohistochemistry.** Tissue sections were prepared and analyzed as described previously (34). After blocking, samples were incubated with the fluorescent dye- or biotin-conjugated antibodies described in SI Materials and Methods and then mounted with PermaFluor (Shandon). Bone marrow sections were prepared using the film method (37). Confocal microscopy was performed with TSC-SPS and TSC-SP8 microscopes (Leica Microsystems).

**Real-Time RT-PCR.** Total RNA was extracted from sorted cells using Sepasol reagent (Nacalai) and from fixed samples using an RNeasy FFPE kit (Qiagen). cDNA was synthesized with random primers and amplified in duplicate by QuantiTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). PCR efficiency was normalized with the QuantiTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). PCR efficiency was normalized using cDNA of whole thymus or bone marrow from WT mice. Primer sequences were as follows: IL-15 forward, 5′-GTGACTTTCATCCCAGTTGC-3′; 5′-TTCC-TTCCAGGGCCAGATTCT-3′; CXCL12, 5′-GAGCCAACGTCACAGACATGCT-3′ and 5′-CCGGTGTAATGCACTACGTC-3′.

7. Mattes I, Schiavoni G, Belardelli F, Tough D (2001) IL-15 is expressed by dendritic cells and from fixed samples using an RNeasy FFPE kit (Qiagen). cDNA was synthesized with random primers and amplified in duplicate by Quant iTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). PCR efficiency was normalized with the QuantiTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). PCR efficiency was normalized using cDNA of whole thymus or bone marrow from WT mice. Primer sequences were as follows: IL-15 forward, 5′-GTGACTTTCATCCCAGTTGC-3′; 5′-TTCC-TTCCAGGGCCAGATTCT-3′; CXCL12, 5′-GAGCCAACGTCACAGACATGCT-3′ and 5′-CCGGTGTAATGCACTACGTC-3′.

7. Mattes I, Schiavoni G, Belardelli F, Tough D (2001) IL-15 is expressed by dendritic cells and from fixed samples using an RNeasy FFPE kit (Qiagen). cDNA was synthesized with random primers and amplified in duplicate by Quant iTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). PCR efficiency was normalized with the QuantiTect SYBR Green PCR kit (Qiagen) with ROX (Invitrogen) using an ABI 7500 sequence detector (Applied Biosystems). SI Materials and Methods

Generation of IL–15–CFP Knock-in Mice. The targeting vector for IL-15–CFP knock-in mice was generated as follows. A diphtheria toxin A cassette was subcloned in the pBluescript KS (+) vector (pBS-DTA). A 1,977-bp genomic DNA fragment of 3’ IL-15 region after the third IL-15 exon was amplified by PCR and subcloned in the pBS-DTA vector (pBS-3’IL15-DTA). The enhanced CFP cassette and neomycin resistance gene cassette flanked by two loxP sites (LNL) were amplified by PCR and inserted into the pBS-3’IL15-DTA vector (pBS-CFP-LNL-3’ IL15-DTA). A 7,999-bp genomic DNA fragment of the 5’ IL-15 region upstream of the initiation codon in the third IL-15 exon was amplified by PCR and subcloned into the pBS-CFP-LNL-3’ IL15-DTA vector (pBS-5’IL15-CFP-LNL-3’IL15-DTA; Fig. S1A). The linearized targeting vector was introduced into the KY1.1 embryonic stem cell line derived from a C57BL/6J×129S6/SvEv-Tac mouse embryo (gift from Junji Takeda, Osaka University, Osaka, Japan). Homologous recombinants were screened by PCR and confirmed by Southern blot analysis with a 3’ probe (Fig. S1B). Targeted ES clones were microinjected into ICR eight-cell embryos. Chimeric mice were bred with CAG-Cre transgenic mice to delete the neomycin cassette. Resultant mice containing homologous recombinants were screened by PCR and confirmed by Southern blot analysis with the 3’ probe shown in Fig. S1. Resultant mice containing the enhanced CFP cDNA within the endogenous IL-15 locus were backcrossed to C57BL/6 mice for at least six generations.

Multiphoton Tissue Imaging. Intravital imaging of mouse calvaria bone was realized as described previously (1, 2). In brief, the frontoparietal regions of the calvaria of anesthetized mice were exposed and fixed on a customized microscope stage. The bone marrow cavity was observed by using a multiphoton imaging microscope. Image stacks were collected at 2 μm vertical step size at a depth of 100 to 150 μm below the skull bone surface. Multiphoton imaging of thymus was performed on explanted tissues with the multiphoton inverted microscope as described for calvaria. Raw imaging data were processed with NIS-Elements software (Nikon) and analyzed using Imaris software (Bitplane) with a Gaussian filter for noise reduction.

Antibodies. The following fluorescent dye- or biotin-conjugated antibodies were used: anti-GFP, Alexa Fluor 488–anti-GFP, Alexa Fluor 546–anti-rabbit IgG, and streptavidin–Alexa Fluor 488 (BioLegend); alkaline phosphatase (APC)–Cy7–anti-CD45, APC–Cy7–anti-CD11c, APC–Cy7–anti-CD11b, Alexa Fluor 647–anti-Ly51, PE–anti-EpCAM, Pacific Blue–anti-MHC-II, APC–anti-CD31, Brilliant Violet 421–anti-CD31, APC–anti-CD140b (PDGFβR), PE–Cy7–anti-Scalc1, biotin–anti-Podoplanin (gp38), and APC–anti-CD3 (Invitrogen); eFluor 450–anti-CD8, APC–Cy7–anti-B220, PE–anti-CD11c, FITC–anti-F4/80, biotin–anti-rat IgG, and PE–or APC–streptavidin (eBioscience); and FITC–anti-CD31, APC–anti-CD11c, and APC–anti-CD11b (BD Pharmingen). Biotin–anti–VCAM-1 was a gift of Tatsuo Kina (Kyoto University, Kyoto, Japan).

Fig. S2. IL-15 expression in thymus and bone marrow. (A) Multiphoton fluorescence in vivo images of the IL-15–CFP knock-in thymus with CFP-labeled cells (turquoise; Left) and collagen fibers visualized by SHG signals (dark blue; Right). (B) Immunohistochemical analysis to detect IL-15 expression in dendritic cells (DCs) and macrophages of IL-15–CFP knock-in thymus (arrowheads). DCs and macrophages were stained with anti-CD11c (blue) and anti-CD11b (blue) antibodies. (Scale bar, 50 μm.) (C) Multiphoton fluorescence in vivo images of the bone marrow with CFP-labeled cells (turquoise; Left) and the bone matrix visualized by SHG signals (dark blue; Right) and blood vessels stained with nanocrystals (purple; Right). Data represent two independent experiments with similar results. (Scale bar, 40 μm.) (D) Multiphoton fluorescence in vivo images of the IL-15–CFP/IL-7–GFP double knock-in bone marrow with CFP-labeled cells (turquoise; Left), GFP-labeled cells (green; Middle), and the bone matrix visualized by SHG signals (dark blue; Right) and blood vessels stained with nanocrystals (purple; Right). Data represent two independent experiments with similar results. (Scale bar, 40 μm.)

Fig. S3. IL-15 expression in hematopoietic subsets of lymph nodes and spleen. IL-15 expression in lymph nodes and spleen of 6- to 10-wk-old IL-15–CFP knock-in mice (IL-15CFP/+) and control WT littermates. CFP signals were detected with anti-GFP antibody. (A) Immunohistochemical analysis of DCs in lymph nodes (arrowheads). DCs were stained with anti-CD11c (blue) antibody. (Scale bar, 50 μm.) (B) Immunohistochemical analysis of macrophages in lymph nodes (arrowheads). Macrophages were stained with anti-CD11b (blue) antibody. Triple stained (red, green, and blue overlap) cells appear white. (Scale bar, 50 μm.) (C) Separation of DC subsets. (D) IL-15 expression in CD8+ and CD8− conventional DCs (cDCs; CD11c+ B220−) and plasmacytoid DCs (pDCs; CD11c+B220+). Data represent three independent experiments with similar results.
Fig. S4. IL-15 expression in lymph node stromal cells during aging. Single cells were isolated from axillary, cervical, and inguinal lymph nodes of 1-, 3- and 10-mo-old IL-15–CFP knock-in mice (IL-15CFP/+ ) and control WT littermates. Percentages of CFP<sup>high</sup> stromal cells are shown. Values are the mean ± SEM of three independent experiments.

Fig. S5. IL-15 induction in DC subsets after LPS administration. (A) Separation of DC subsets. (B) IL-15 expression in DC subsets from 6- and 10-wk-old IL-15–CFP knock-in mice and control WT littermates 3 d after injection of PBS solution (control; Upper) or LPS (Lower). (C) The difference in mean fluorescence intensity (ΔMFI) values of CFP between LPS-stimulated and nonstimulated mice as shown in B. Values are the mean ± SEM of three independent experiments.

Fig. S6. Elimination of hematopoietic cells in flow cytometric analysis. (A) CD45 expression in hematopoietic subsets. Flow cytometric analysis of spleen cells 3 d after injection of PBS solution or LPS. (B) CD45<sup>−</sup>CD11b<sup>−</sup>CD11c<sup>−</sup> gated stromal cell fractions in lymph nodes and spleen. Data represent at least three independent experiments with similar results.
Fig. S7. IL-15 expression in heart and liver. IL-15 expression in heart and liver of 6- to 12-wk-old IL-15−CFP knock-in mice (IL-15CFP/+ and control WT littermates. CFP signals were detected with anti-GFP antibody. (A) Immunohistochemical analysis of heart. Endothelial cells were stained with anti-CD31 antibody. CFP+ CD31+ cells (blue and green overlap) appear turquoise. (B) Immunohistochemical analysis of liver. Macrophages and endothelial cells were stained with anti-F4/80 and anti-CD31 antibodies, respectively. (C) Immunohistochemical analysis of liver 3 d after LPS injection. CFP+ macrophages (red and green overlap) appear yellow. Data represent two independent experiments with similar results. (Scale bar, 50 μm.)
