Abstract

We herein report a case of a renal pelvic tumor that developed in the residual left renal pelvis after right nephroureterectomy, left ureterectomy, and total cystectomy in a patient with multiple urothelial tumors. The tumor was endoscopically ablated via a nephrostomy tract, and mitomycin C irrigation was performed. We designed a novel constant-pressure irrigation system for effective and safe irrigation into the closed space of the renal pelvis. We created a hole in the urine bag tube, inserted a 5-F open-end ureteral catheter via the hole, and kept the tip of the catheter at the end of the nephrostomy tube. The urine bag tube was placed 20 cm above the kidney level, and mitomycin C was continuously irrigated into the renal pelvis for 1 hour. Six weekly treatments were performed, and tumor recurrence was not identified for 1 year.

Introduction

Nephroureterectomy with open excision of the bladder cuff remains the gold standard treatment for upper urinary tract urothelial carcinoma¹. However, because of concerns about preservation of renal function or the inability of

patients to tolerate surgery, a select group of patients may be suitable for organ-preserving treatment.

We herein present a novel constant-pressure irrigation technique. Because this irrigation system would allow for the increased performance of organ-preserving treatment, general urologists will find this manuscript very useful.

Methods

A 63-year-old man had undergone four transurethral resections for the treatment of superficial bladder tumors from 2007 to 2009. Histological examinations revealed grade 2 pT1 tumors together with carcinoma in situ (CIS). He didn't have any risk factors of multifocal urothelial carcinoma, such as smoking. In 2009, right renal pelvic tumors, left lower ureteral tumors, and bladder CIS were found by contrast-enhanced computed tomography (CECT) and cystoscopy. Total cystectomy and bilateral nephroureterectomy were recommended. However, the patient refused this treatment option because of his strong desire to avoid hemodialysis. Therefore, right nephroureterectomy, left ureterectomy, total cystectomy, and

left nephrostomy were performed. Histological examination revealed grade 2 pT3 papillary urothelial carcinoma in the right renal pelvis and grade 2 pTa/is papillary urothelial carcinoma in the left ureter and the bladder, and combination chemotherapy using methotrexate, epirubicin, and cisplatin was performed. After 2 years of follow-up, the patient's urinary cytology result was positive, and a solitary left renal pelvic tumor was found by CECT. The tumor was endoscopically ablated using a 22-F flexible cystoscope. Histological examination revealed grade 2 pTa papillary urothelial carcinoma. A 22-F nephrostomy tube was inserted after the surgery, and adjuvant mitomycin C irrigation into the residual renal pelvis via the nephrostomy tube was scheduled. Because the renal pelvis was a closed space after the ipsilateral ureterectomy, an irrigation catheter was essential for safe and effective treatment. However, to our knowledge, no appropriate catheter is available, such as a three-way Foley catheter for bladder irrigation. Therefore, we created a novel constant-pressure irrigation system using a nephrostomy catheter, urine bag, and open-end ureteral catheter (Figure 1).

Our technique for mitomycin C irrigation was performed with the patient in

the supine position. A small hole was made in the middle of the urine bag tube, and a 5-Fr open-end ureteral catheter was inserted into the hole. Using the fluoroscope, the tip of the ureteral catheter was kept at the end of the nephrostomy catheter. At first, contrast media was irrigated at 100 ml/h, and we fluoroscopically confirmed that the renal pelvis was perfused by the contrast media. To maintain a constant pressure in the renal pelvis, the distance between the kidney and the urine bag tube was kept at 20 cm. Under these conditions, renal pelvic irrigation was performed using mitomycin C. A bottle of 40 mg mitomycin C dissolved in 100 ml of 0.9% saline was irrigated via the ureteral catheter for 1 hour (Figure 2). Six weekly treatments were performed. The serum creatinine concentration was 1.3 to 1.5 mg/dl during the treatment period and 1.3 mg/dl 1 year after treatment. One year after the treatment, no recurrence or metastasis was identified.

Discussion

Instillation therapy can be accomplished in several ways. Accepted techniques include antegrade instillation through a nephrostomy tube² and

retrograde instillation directly into a ureteral catheter³ or by reflux through an indwelling ureteral stent or iatrogenically created vesicoureteral reflux^{4,5}.

Patel described a convenient technique of outpatient instillation through a ureteral catheter placed suprapubically⁶.

The role of intravesical immunotherapy using bacillus Calmette-Guerin (BCG) or chemotherapy using mitomycin C for non-muscle-invasive urothelial carcinoma of the bladder has been established. However, the role of instillation therapy for upper urinary tract tumors has been equivocal, and its long-term effectiveness has not been elucidated⁷.

To the best of our knowledge, this is the first reported case of creation of an irrigation technique for the treatment of renal pelvic tumors in a solitary kidney after ipsilateral ureterectomy. The advantages of this technique are (1) the application of constant low pressure to minimize the risk of bacterial sepsis or systemic absorption of the agent, (2) contact of all urothelium with instillation media, (3) ability to repeat instillation therapy at low cost, and (4) safety of collecting the instillation media in the bag. It was considered that some selected multiple urothelial cancer patients might have chance to avoid bilateral nephroureterectomy using this technique.
