Kyoto University
Transformation of Organic Molecules

Based on Ring Opening of Four-Membered Carbon Skeletons

Shota Sawano

2015
Preface

The studies presented in this thesis have been carried out under the direction of Professor Masahiro Murakami at Kyoto University from April 2009 to July 2015. The studies are concerned with transformations of organic molecules through the ring opening of four-membered carbon skeletons.

The author would like to express his sincerest gratitude to Supervisor Professor Masahiro Murakami for his continuous guidance, encouragement, and stimulating discussions throughout this study. All the works in this thesis could be achieved with his constant supervisions.

The author would like to express the deepest appreciation to Assistant Professor Naoki Ishida for his kind support, continuous encouragement, and teaching chemical techniques. The author also owes his sincerest gratitude to Associate Professor Tomoya Miura and Assistant Professor Akira Yada for their helpful suggestions, directions, and encouragement.

The author fortunately had the great assistance of Mr. Yusuke Masuda and Mr. Norikazu Ishikawa. The author would like to offer his special thanks to them for their enormous contribution.

The author wishes to show his gratitude to Dr. Masanori Shigeno, Dr. Motoshi Yamauchi, Dr. Takeharu Toyoshima, Mr. Tomohiro Igarashi, Mr. Keita Ueda, Mr. Taisaku Moriya, Dr. Yasuhiro Shimamoto, Dr. Masao Morimoto, Mr. Osamu Kozawa, Mr. Wataru Ikemoto, Mr. Akira Kosaka, Mr. Tsuneaki Biyajima, Mr. Yusuke Mikano, Mr. Yuuta Nakanishi, Ms. Yui Nishida, Mr. Kentaro Hiraga, Mr. Tatsuya Yuhki, Ms. Hanako Sunaba, Mr. Takamasa Tanaka, Mr. Tetsuji Fujii, Mr. Yuuta Funakoshi, Mr. Shintaro Okumura, Mr. Takayuki Nakamuro, Mr. Shoichiro Fujita, Mr. Yuuki Yamanaka, Mr. Shoki Nishi, Mr. Kohei Matsumoto, Mr. Satoshi Okajima, Mr. Yoshikazu Fujimoto, Mr. Qiang Zhao, Ms. Yumi Ishihara, Mr. Sho Uemoto, Mr. Yuuta Sato, Mr. Junki Nakahashi, Mr. Hiroki Nikishima, Mr. Fangzhu Sun, Mr. Wenqing Liao, Mr. Yuuya Imamura, Mr. Kohei Hagiwara, Mr. Sho Miyakawa, Dr. Lantao Liu, Dr.
Changkun Li, Dr. David Nečas, Dr. Scott G. Stewart, Dr. Chia-Jung Liang, Mr. Andreas Fetzer, Ms. Kana Kunihiro, and all other past members of Murakami group for their enthusiasm and kind consideration.

The author expresses his heartfelt appreciation to Ms. Yuki Sakai for her generous support.

The author is deeply grateful to Professor Michinori Suginome, Associate Professor Toshimichi Ohmura, Assistant Professor Yuuya Nagata and Takeshi Yamamoto, Dr. Yuto Akai, and all other members of Suginome’s laboratory for their hospitality.

The author thanks Mr. Tadashi Yamaoka, Mr. Haruo Fujita, Ms. Eriko Kusaka, Ms. Keiko Kuwata, and Ms. Karin Nishimura for supporting his research such as the measurement of NMR spectra and Mass spectra.

The author is thanking Professor Richmond Sarpong for giving him a precious opportunity to participate in the chemical research at University of California, Berkeley.

The author would also like to express his gratitude to the foundation of Advanced Catalytic Transformation program for Carbon utilization for the financial support.

Finally, the author would like to show his greatest appreciation to his family, especially his parents, Mr. Shingo Sawano and Ms. Akiko Sawano for their constant assistant, support, and encouragement.

General Introduction

Four-membered ring. Selective cleavage of abundant C–C bonds have attracted a lot of interest in the field of organometallic chemistry, which could provide organic molecules in an atom-economical manner. Although the cleavage of a C–C bond is a challenging subject owing to their thermodynamic stability as well as their kinetic inertness, four-membered ring skeletons are well utilized to access to diverse carbon frameworks via C–C bond cleavage. This is because the release of strain energy is available to progress an elementary step of the C–C bond cleavage forward thermodynamically. In addition, HOMO and LUMO of C–C σ-orbital in four-membered ring are similar to those of C=C π-orbital due to structural distortion. These distinct orbitals assist a metal complex to interact with a C–C bond to reduce the kinetic barrier. There have been a number of publications about C–C bond cleavage of four-membered ring to date, the author would like to provide a brief introduction about catalytic transformations of cyclobutane derivatives for the background of his thesis.

Early works. Catalytic transformations based on the ring opening of a four-membered ring have been developed since around 1990. Liebeskind et al. reported a nickel-catalyzed reaction of cyclobutenone derivatives in 1991 (Scheme 1a). In this case, a nickel complex cleaved a C–C bond of cyclobutenone to afford a substituted phenol through the insertion of alkyne. In 1994, Murakami, Amii, and Ito have found that a rhodium complex also cleaved a C–C bond of cyclobutanone derivatives catalytically (Scheme 1b). In this report, a rhodium complex was inserted into a C–C bond adjacent to a carbonyl group selectively via oxidative addition. With this result as a trigger, Murakami group has mainly developed the synthetic transformations via the C–C bond cleavage of cyclobutane frameworks with the use of a rhodium catalyst.

\]

Ring opening of cyclobutanols. Transition metal-catalyzed reactions of cyclobutanols construct a wide variety of carbon skeletons via ring opening of the cyclobutane ring. Mechanistically, these transformations proceed through the formation of a metal cyclobutanolate via ligand exchange, followed by β-carbon elimination in which a carbon atom on γ-position migrates onto metal center with the cleavage of the C–C bond between β- and γ-positions (Scheme 2). Not only the release of the strain but also the generation of the carbonyl group are crucial to proceed this elementary process forward. It may be assumed that an agostic interaction plays an important role for β-carbon elimination although there has been no report about the direct observation of such an interaction.

In 1999, Uemura et al. reported the first example concerned with ring opening of cyclobutanols via β-carbon elimination in the presence of a palladium catalyst. They also developed the asymmetric synthesis of β-arylated ketone through the enantioselective C–C bond cleavage by a chiral palladium-catalyzed reaction of cyclobutanols with aryl halides. On the other hand, Murakami group found a rhodium catalyst also induced ring opening of a cyclobutanol. The generating rhodium cyclobutanolate undergoes ring opening through β-carbon elimination to furnish (δ-ketoalkyl)rhodium(I) species. Since this species shows a unique reactivity dependent on the structure of starting materials, there have been developed synthetic transformations based on a rhodium-catalyzed reaction of cyclobutanol derivatives. The detail will be mentioned in chapter 1.
Scheme 2. Ring opening of cyclobutanols via $\beta$-carbon elimination

Ring opening of benzocyclobutenols. Unlike cyclobutanols, benzocyclobutenols are known to cleave their C–C bonds in the absence of transition metals. Thermal reaction of benzocyclobutenols induces the distal C(sp$^3$)–C(sp$^3$) bond cleavage via 4$\pi$ electron cyclization reaction (Scheme 3).$^{13}$ Since the generating o-quinodimethanes subsequently engage in [4 + 2] cycloaddition with dienophiles,$^{14}$ benzocyclobutenol derivatives have been utilized for the synthesis of natural products$^{15}$ and functional materials$^{16}$.

Scheme 3. Ring opening of benzocyclobutenol under thermal condition

On the other hand, benzocyclobutenols sometimes undergo ring opening with the cleavage of the proximal C(sp$^2$)–C(sp$^3$) bond in prior to the distal C(sp$^3$)–C(sp$^3$) bond.$^{17}$ For example, when a chloro-substituted benzocyclobutenol is treated with a base, the proximal C(sp$^2$)–C(sp$^3$) bond is cleaved (Scheme 4a).$^{17b}$ A palladium catalyst also induces the site-selective ring opening of the proximal C(sp$^2$)–C(sp$^3$) bond (Scheme 4b).$^{17d}$

Scheme 4. Ring opening of benzocyclobutenols
(a) Basic condition
(b) Palladium-catalyzed reaction

![Reaction Scheme](image)

Previously, Murakami group developed a rhodium-catalyzed reaction of 1-chlorobenzocyclobutene with phenylboronic acid (Scheme 4b). The major ring-opening product is yielded via the cleavage of the proximal C(sp²)–C(sp³) bond. The reaction mechanism is as follows; (1) generation of a phenyl rhodium species by transmetalation, (2) insertion of a carbonyl group into the C(sp³)–Rh bond to furnish a rhodium benzocyclobutanolate, (3) β-carbon elimination to open the cyclobutene ring, and (4) protonation. This result shows that a rhodium benzocyclobutenolate prefers the cleavage of the proximal C(sp³)–C(sp³) bond in prior to the distal C(sp³)–C(sp³) bond. Chapter 2 and after, the author examines a rhodium-catalyzed reaction of benzocyclobutenols, which would generate rhodium benzocyclobutenolates.

Scheme 5. Rhodium-catalyzed reaction of benzocyclobutenones

![Scheme 5](image)

Overview of this thesis. Herein is disclosed the development of new synthetic transformations based on the ring opening of cyclobutanols and benzocyclobutenols. The outline is shown in the following.

Chapter 1 is shown a rhodium-catalyzed reaction of 1-(2-haloaryl)cyclobutanols to produce 3,3-disubstituted-α-tetralones (Scheme 6). The reaction mechanism is estimated as follows; (1) deprotonation to form a rhodium cyclobutanolate(I), (2) oxidative addition to furnish a five-membered rhodacycle(III), (3) β-carbon elimination to induce ring opening leading to seven-membered rhodacycle(III), and (4) reductive elimination to afford α-tetralone. This reaction can be extended to the asymmetric synthesis of 3,3-disubstituted-α-tetralones through the enantioselective cleavage of the C–C bond in the presence of a chiral rhodium catalyst.
Scheme 6. Rhodium-catalyzed reaction of 1-(2-haloaryl)cyclobutanols

![Diagram of the reaction](image)

Chapter 2 deals with a rhodium-catalyzed reaction of benzocyclobutenols. In contrast to the thermal reaction, the proximal C(sp²)–C(sp³) bond is cleaved selectively in the presence of a rhodium catalyst (Scheme 7a). The reaction mechanism is shown as follows: (1) ligand exchange to furnish a rhodium benzocyclobutenolate, (2) β-carbon elimination to generate arylrhodium species, and (3) protonation to yield the ring-opening product. This site-selective ring opening leads to the development of a new alkyne insertion reaction to form a dihydronaphthalene framework. A triple bond of alkyne is inserted into the proximal C(sp²)–C(sp³) bond selectively (Scheme 7b).

Scheme 7. Ring opening of benzocyclobutenols
(a) Thermal reaction vs. Rhodium-catalyzed reaction

![Diagram of the reaction](image)

(b) Reaction with alkynes

![Diagram of the reaction](image)

In chapter 3, the author shows a rhodium-catalyzed reaction of benzocyclobutenols with electron-deficient alkenes to construct tetralin skeletons (Scheme 8). In the same way as a rhodium-catalyzed reaction of benzocyclobutenols with alkynes shown in chapter 2, a double bond of electron-deficient alkene is inserted into the proximal C(sp³)–C(sp³) bond with site-selectivity. The produced structures make a remarkable contrast with those available from the identical compounds under thermal reaction
conditions. Mechanistically, the generating arylrhodium species undergoes conjugate addition across an electron-deficient alkene, followed by intramolecular aldol reaction and sequential protonation. The author also demonstrates the synthesis of 2-tetralone skeletons through the rhodium-catalyzed reactions of 1-alkenylbenzocyclobutanols.

**Scheme 8.** Thermal ring expansion vs. Rhodium-catalyzed ring expansion

In chapter 4, ring expansion of orthocyclophane to metacyclophane is described (Scheme 9a). This transformation is achieved by sequential action of light and a rhodium catalyst. Non-strained C–H and C–C bonds are cleaved and exchanged in a formal sense without elimination of any leaving groups. Although the product is energetically uphill from the starting material, the endergonic photocyclization step enables to drive the transformation forward. A rhodium-catalyzed reaction of a tricyclic benzocyclobutenol possessing central chirality with methyl vinyl ketone yields a metacyclophane possessing planar chirality (Scheme 9b). This reaction proceeds shown in the following; (1) deprotonation to generate a rhodium benzocyclobutanolate with central chirality, (2) β-carbon elimination to furnish arylrhodium species with planar chirality, and (3) conjugate addition to methyl vinyl ketone to generate oxa(π-allyl)rhodium species, and (4) protonation to yield planar chiral metacyclophane. Central-to-planar chirality transfer occurs during the C–C bond cleavage by β-carbon elimination.

**Scheme 9.** Synthesis of metacyclophanes

(a) Ring expansion from orthocyclophanes to metacyclophanes
(b) Central-to-planar chirality transfer

In chapter 5, the author examines a palladium-catalyzed hydrogenolysis of alkoxybenzocyclobutenes (Scheme 10). The cyclobutene ring is opened with the cleavage of the proximal C(sp\(^2\))–C(sp\(^3\)) bond selectively although a palladium on carbon catalyst is often utilized to cleave a C(sp\(^3\))–C(sp\(^3\)) bond of small cycloalkane and a C–O bond of benzyl ether.

Chapter 1

Synthesis of 3,3-Disubstituted α-Tetralones
by Rhodium-Catalyzed Reaction of 1-(2-Haloaryl)cyclobutanols

Abstract
A rhodium-catalyzed reaction of 1-(2-haloaryl)cyclobutanols induced the ring opening of the cyclobutane to form 3,3-disubstituted-α-tetralones. This reaction might proceed through 1) formation of a rhodium(I) cyclobutanolate via ligand exchange, 2) generation of a five-membered rhodacycle(III) via oxidative addition, 3) β-carbon elimination to furnish seven-membered rhodacycle(III), and 4) reductive elimination. Asymmetric synthesis of 3,3-disubstituted-α-tetralone was also achieved in the presence of a chiral rhodium catalyst.
Chapter 1

Introduction

Palladium\(^1\) and rhodium-catalyzed\(^2\) reactions of cyclobutanols\(^3\,^4\) construct a variety of carbon frameworks dependent on the transition metals and the substituents. For example, rhodium cyclobutanolates undergo ring opening by β-carbon elimination to generate (δ-ketoalkyl)rhodium(I) species, with which three pathways are known to proceed. When a 3,3-dialkyl-substituted cyclobutanol is employed as the starting substrate, the resulting alkylrhodium(I) intermediate undergoes a 1,3-rhodium shift to form a rhodium enolate, protonation of which furnishes an acyclic ketone.\(^2\) On the other hand, in the case that an aryl group is attached to the 3-position, a 1,4-rhodium shift occurs with the ring-opened (δ-ketoalkyl)rhodium(I) species to furnish an arylrhodium(I) intermediate, which intramolecularly adds to the carbonyl group to afford indanols.\(^2\) When a cyclobutanol has an alkene or allene substituent at the 1-position, the alkylrhodium(I) intermediate undergoes 1,2-addition across the carbon–carbon double bond, leading to the formation of cyclohexanones or cyclohexenones.\(^2\)

Herein is disclosed a rhodium-catalyzed reaction of cyclobutanols possessing an o-bromoaryl moiety at the 1-position, which furnishes 3,3-disubstituted α-tetralones. Unlike the previous examples, the reaction mechanism involves a rhodium(I)/(III) oxidation/reduction process.

Results and Discussions

When a dioxane solution of 1-(2-bromophenyl)-3,3-diphenylcyclobutanol (1a) was heated at 120 °C in the presence of [Rh(OH)(cod)]\(_2\) (5 mol %), DPPB (11 mol %) and K\(_3\)PO\(_4\) (1.1 equiv) for 15 h, α-tetralone 2a was obtained in 96% isolated yield (Scheme 1).\(^5\) No formation of acyclic ketone 3a and indanol 4a was detected by GC-MS analysis of the reaction mixture. This result suggests that the intermediacy of the ring-opened (δ-ketoalkyl)rhodium species is unlikely.\(^2\)

Scheme 1. Rhodium-catalyzed reaction of cyclobutanol 1a
The following experiments were carried out in order to provide information for mechanistic interpretation of the reaction pathway (Scheme 2). When the same reaction conditions were applied to cyclobutanol 1b without a bromo group on the phenyl ring, indanol 4b was obtained as a sole product (84% yield).\textsuperscript{2b,c} The reaction of 1b with bromobenzene also afforded indanol 4b in 83% yield. Bromobenzene did not react with all rhodium species generated in this catalytic cycle. This result shows in marked contrast to that obtained with a palladium(0) catalyst; bromobenzene participates in the palladium-catalyzed reaction of cyclobutanol 1b to form a δ-arylated ketone.\textsuperscript{2d} The contrasting results indicate that rhodium(I) is far less reactive towards bromobenzene than palladium(0).\textsuperscript{6} Overall, the presence of the bromo group within the cyclobutanol skeleton dictated the reaction pathway to a new direction, \textit{i.e.}, to the formation of α-tetralones.

**Scheme 2. Rhodium-catalyzed reaction of cyclobutenol 1b**

On the basis of these results, the author proposes a possible mechanism for the formation of 2a from 1a as depicted in scheme 3. Cyclobutanol 1a initially reacts with a rhodium(I) complex in the presence of a base to generate rhodium(I) cyclobutanolate A. The rhodium(I) center is geometrically constrained in proximity to the bromoaryl group, and thus, an oxidative addition process is facilitated to give five-membered rhodacycle(III) B.\textsuperscript{7} Then, the four-membered carbocycle is opened by β-carbon elimination to afford seven-membered rhodacycle(III) C.\textsuperscript{8} Finally, reductive elimination provides α-tetralone 2a with regeneration of the rhodium(I) catalyst.
Other cyclobutanols bearing an o-haloaryl group at the 1-position were subjected to the rhodium-catalyzed reaction conditions (Table 1). Cyclobutanols having alkyl and aryl substituents at the 3-position participated in the reaction to give α-tetralones in good yields (entries 1–3). On the other hand, cyclobutanols with the 3-position being unsubstituted provided a complex mixture, probably due to the concurrence of β-hydride elimination with intermediate C. The azetidin-3-ol could be employed instead of cyclobutanols to furnish isoquinolinone 2f in 69% yield (entry 4). Both electron-donating and -withdrawing groups were admitted on the aryl ring (entries 5–7). An iodo counterpart of 1c underwent the reaction at 100 °C to form 2c in 72% yield, indicating that aryl iodides were more reactive than aryl bromides. In contrast, the reaction of the chloro analogue of 1a was much slower. The product 2a was obtained in 42% yield with the unreacted starting compound remaining even after 48 h. The reaction of the cyclobutanol bearing an o-bromobenzyl group gave a complex mixture. These results revealed the importance of the geometrical constraint as well as the reactivity toward oxidative addition of the haloaryl moiety.

\textsuperscript{a} Reaction conditions: 1.0 equiv cyclobutanol 1, 5 mol % [Rh(OH)(cod)]\textsubscript{2}, 11 mol % DPPB, 1.1 equiv K\textsubscript{3}PO\textsubscript{4}, dioxane (0.2 M), 120 °C, 24 h unless otherwise noted. \textsuperscript{b} Isolated yields. \textsuperscript{c} A diastereomer mixture of 1 was used. \textsuperscript{d} 11 mol % BINAP was employed instead of DPPB. \textsuperscript{e} DMSO was employed instead of dioxane. \textsuperscript{f} The reaction was conducted at 0.1 M, 150 °C. \textsuperscript{g} Heated for 63 h.

Next was examined the asymmetric synthesis of 3,3-disubstituted-\(\alpha\)-tetralones. By screening various chiral ligands, tol-BINAP exhibited a fairly good enantioselectivity (Scheme 4). When cis-1d was treated with a Rh(I)/(R)-tol-BINAP catalyst in dioxane, (+)-2d was obtained in 72% yield with 87% ee. On the other hand, the other diastereomer trans-1d afforded the opposite enantiomer (−)-2d in 69% yield with 81% ee. Both enantiomers were converted to the corresponding tetralins and their absolute configurations were determined by the measurement of optical rotations.\textsuperscript{9} These results suggest that the (R)-tol-BINAP ligand favored the cleavage of the bond a located on the right in the drawings of scheme 4, irrespective of the stereochemical arrangement at the 3-position.
Scheme 4. Asymmetric synthesis of 3,3-disubstituted-α-tetralones

**Conclusions**

The author has developed a rhodium-catalyzed reaction of 3,3-disubstituted 1-(2-haloaryl)cyclobutanols, which provides 3,3-disubstituted α-tetralones with a quaternary carbon center in an enantiomerically enriched form. The author failed to find such chiral α-tetralones by structural search on electronic databases, which was probably owing to the paucity of an appropriate synthetic method. Asymmetric conjugate addition of carbon nucleophiles to α,β-unsaturated carbonyl compounds is an authentic method for introducing a chiral center at the position β to a carbonyl group. However, α-tetralones bearing a chiral quaternary carbon at the 3-position are inaccessible via conjugate addition to dehydrotetralone because 1-naphthol is the more stable tautomer of dehydrotetralone and unreactive as the conjugate acceptor. Therefore, the rhodium-catalyzed reaction shown here would serve as a useful synthetic method for such chiral α-tetralone derivatives.
Experimental section

General. All reactions were carried out under a nitrogen atmosphere unless otherwise noted. Infrared spectra were recorded on a Shimadzu FTIR-8400 spectrometer. $^1$H and $^{13}$C NMR spectra were recorded on a Varian Mercury vX400 ($^1$H at 400 MHz and $^{13}$C at 100 MHz) spectrometer using CDCl$_3$ ($^1$H, δ = 7.26) and CDCl$_3$ ($^{13}$C, δ = 77.0) as an internal standard unless otherwise noted. High-resolution mass spectra were recorded on a Thermofisher EXACTIVE (APCI and ESI). Optical rotation was measured by a JASCO P-1020 polarimeter with a sodium lamp. HPLC analysis was performed by 4.6 x 250 mm column. Gel permeation chromatography (GPC) was carried out with a Japan Analytical Industry LC-9204. Recycling preparative HPLC was carried out with a Japan Analytical Industry LC-9110 NEXT SERIES. Flash column chromatography was performed with silica gel 60 N (Kanto). Preparative thin-layer chromatography was performed on silica gel plates with PF254 indicator (Merck).

Materials. 1,4-dioxane was distilled from sodium/benzophenone ketyl. [Rh(OH)(cod)]$_2$ was prepared according to the literature procedure. The cyclobutanones were prepared by [2+2] cycloaddition of the corresponding olefins with dichloroketene and subsequent dechlorination with zinc dust in acetic acid. Cyclobutanol 1b was prepared according to the literature procedure. All other commercially available chemical reagents were used as received without further purification.

General procedure for the synthesis of 1-(2-haloaryl)cyclobutanols

To a stirred solution of 2-bromiodobenzene (1.2 equiv) in THF at −78 °C was added i-PrMgBr in THF (1.2 equiv) slowly. After stirring for 2 h, a solution of cyclobutanone (1.0 equiv) in THF was added dropwise to the reaction mixture at −78 °C, then warmed to room temperature. After the starting material was consumed, saturated NH$_4$Cl aq was added. The mixture was extracted with Et$_2$O, washed with water and brine, dried over Na$_2$SO$_4$, and evaporated. After the purification by flash column chromatography on silica gel or gel permeation chromatography, 1-(2-haloaryl)cyclobutanol was obtained.

Rhodium-catalyzed reaction of 1b to form 4b

A mixture containing [Rh(OH)(cod)]₂ (2.2 mg, 5.0 µmol, 5.0 mol %), DPPB (4.7 mg, 11 µmol, 11 mol %), K₃PO₄ (23.3 mg, 0.11 mmol), PhBr (18.8 mg, 0.12 mmol), and 1b (30.0 mg, 0.10 mmol) in 1,4-dioxane (0.50 ml) was stirred at 120 °C for 24 h. After being cooled to room temperature, the reaction mixture was diluted with water and extracted with ethyl acetate. The combined organic phase was washed with H₂O and brine, dried over MgSO₄, and evaporated. The residue was purified by preparative
thin-layer chromatography of silica gel (hexane/ethyl acetate = 10/1) to afford 4b.

**A typical procedure for the rhodium-catalyzed reaction of 1a**

A mixture containing [Rh(OH)(cod)]$_2$ (2.3 mg, 5.0 µmol, 5.0 mol %), DPPB (4.7 mg, 11 µmol, 11 mol %), K$_3$PO$_4$ (23.3 mg, 0.11 mmol), and 1a (37.9 mg, 0.10 mmol) in 1,4-dioxane (0.50 ml) was stirred at 120 °C for 15 h. After being cooled to room temperature, the reaction mixture was diluted with H$_2$O and extracted with ethyl acetate (three times). The combined organic phase was washed with H$_2$O and brine, dried over MgSO$_4$ and evaporated. The residue was purified by preparative thin-layer chromatography of silica gel (hexane/ethyl acetate = 10/1) to afford 2a (28.7 mg, 0.096 mmol, 96%)

Asymmetric synthesis of (+)-2d

A mixture containing [Rh(OH)(cod)]\(_2\) (2.2 mg, 5.0 µmol, 5.0 mol%), \((R)\)-tol-BINAP (7.4 mg, 11 µmol, 11 mol %), K\(_3\)PO\(_4\) (23.3 mg, 0.11 mmol), and cis-1d (29.7 mg, 0.10
mmol) in 1,4-dioxane (0.50 ml) was stirred at 120 °C for 24 h. After being cooled to room temperature, the reaction mixture was diluted with water and extracted with ethyl acetate (three times). The combined organic phase was washed with H₂O and brine, dried over MgSO₄, and evaporated. The residue was purified by preparative thin-layer chromatography of silica gel (hexane/ethyl acetate = 10/1) to afford (+)-2d (15.7 mg, 0.072 mmol, 72%). The enantiomeric excess was determined to be 87% by chiral HPLC analysis [Daicel CHIRALPAK® AS-H column, hexane/i-PrOH = 98/2, 0.4 ml/min, retention times: \( t_1 = 6.7 \) min (major); \( t_2 = 7.0 \) min (minor)].

**Transformation of (+)-2d to (+)-5d**

The CH₂Cl₂ (1.0 ml), propane-1,3-dithiol (40.0 µL, 0.40 mmol), and boron trifluoride diethyl etherate (48.0 µl, 0.38 mmol) were added to the (−)-2d (31.5 mg, 0.14 mmol) in the schlenk and the mixture was stirred for 14 h at 23°C. The reaction mixture was quenched with 2 M aq. NaOH and extracted with Et₂O. The organic layer was washed with water and brine, dried over MgSO₄, and evaporated. The residue was purified preparative thin-layer chromatography of silica gel (hexane/ethyl acetate = 20/1) to give dithiane. A solution of this dithiane in EtOH (1.0 mL) was added to a suspension of Raney-Ni (1 g) in MeOH (1.00 mL) and stirred for 10 h at room temperature. The mixture was filtered over a celite pad. Hexane was added and the organic layer washed with water and brine, and evaporated. The residue was purified preparative thin-layer chromatography of silica gel (hexane only) to give (+)-5d (14.7 mg, 0.073 mmol, 52 % over 2 steps, \([\alpha]_D^{19} = +1.2\)).

**Asymmetric synthesis of (−)-2d**

A mixture containing [Rh(OH)(cod)]₂ (2.2 mg, 5.0 µmol, 5.0 mol%), (R)-tol-BINAP (7.4 mg, 11 µmol, 11 mol %), K₃PO₄ (23.3 mg, 0.11 mmol), and trans-1d (29.7 mg, 0.10 mmol) in 1,4-dioxane (0.50 ml) was stirred at 120 °C for 24 h. After being cooled to room temperature, the reaction mixture was diluted with water and extracted with ethyl acetate (three times). The combined organic phase was washed with H₂O and brine, dried over MgSO₄, and evaporated. The residue was purified by preparative thin-layer chromatography of silica gel (hexane/ethyl acetate = 10/1) to afford (−)-2d (15.0 mg, 0.069 mmol, 69%). The enantiomeric excess was determined to be 81% by chiral HPLC analysis [Daicel CHIRALPAK® AS-H column, hexane/i-PrOH = 98/2, 0.4 ml/min, retention times: \( t_1 = 7.4 \) min (minor); \( t_2 = 7.0 \) min (major)].
Transformation of (−)-2d to (−)-5d

The CH₂Cl₂ (1.0 ml), propane-1,3-dithiol (40.0 µL, 0.40 mmol), and boron trifluoride diethyl etherate (48.0 µl, 0.38 mmol) were added to the (−)-2d (30.0 mg, 0.13 mmol) in the shrenk and the mixture was stirred for 14 h at 23°C. The reaction mixture was quenched with 2 M aq. NaOH and extracted with Et₂O. The organic layer was washed with water and brine, dried over MgSO₄, and evaporated. The residue was purified preparative thin-layer chromatography of silica gel (hexane/ethyl acetate = 20/1) to give dithiane. A solution of this dithiane in EtOH (1.0 mL) was added to a suspension of Raney-Ni (1 g) in EtOH (1.0 mL) and stirred for 10 h at room temperature. The mixture was filtered over a celite pad. Hexane was added and the organic layer washed with water and brine, and evaporated. The residue was purified preparative thin-layer chromatography of silica gel (hexane only) to give (−)-5d (11.8 mg, 0.059 mmol, 45 % over 2 steps, [α]D = −1.3).
Notes and references

5. The results with other ligands at 100 °C for 13 h: PPh₃ (10%), P(t-Bu)₃ (10%), IPr (0%), DPPP (23%), BINAP (30%), DPPB (53%).

6. Although the use of palladium complexes was also examined in the reaction of 1a under various reaction conditions, tetralone 2a was produced in less than 30% yield together with unidentified byproducts.

Chapter 2

Rhodium-Catalyzed Ring Opening of Benzocyclobutenols with Site-Selectivity Complementary to Thermal Ring Opening

Abstract
Benzocyclobutenols are known to undergo thermal ring-opening reactions with the cleavage of the “distal” carbon–carbon bond to furnish reactive o-quinodimetanes. Herein is shown a rhodium-catalyzed ring-opening reaction of benzocyclobutenols, which occurs with the site-selectivity complementary to those of the conventional ring-opening reactions, i.e., with exclusive cleavage of the “proximal” carbon–carbon bond. A new alkyne insertion reaction constructing a dihydronaphthalene framework is developed based on the rhodium-catalyzed proximal carbon–carbon bond cleavage.
**Introduction**

Cyclobutenes undergo thermal and photochemical ring-opening reactions with cleavage of the C(sp\(^3\))–C(sp\(^3\)) bond to form 1,3-dienes.\(^1\) An oxy substituent, in particular an anionic one, accelerates the ring-opening reaction and mediates its own rotational direction (torquoselectivity).\(^2\) Analogously, benzocyclobutenols undergo ring opening with cleavage of the C(sp\(^3\))–C(sp\(^3\)) bond, which the author refers as the “distal” bond (Scheme 1). Heating,\(^3\) photo irradiation,\(^4\) and treatment with a base\(^5\)–\(^7\) induce their ring opening to generate reactive o-quinodimethanes,\(^8\) which subsequently react with dienophiles to yield ring expansion products.\(^9\) This type of [4 + 2] cycloaddition has been utilized for the synthesis of natural products\(^10\) and functional materials.\(^11\) On the other hand, Murakami group previously reported a rhodium-catalyzed reaction of phenylboronic acid onto benzocyclobutenone.\(^12\) The resulting rhodium tert-benzocyclobutenolate intermediate underwent ring opening with cleavage of the “proximal” bond in prior to the distal bond. This preliminary finding led the author to examine ring opening of benzocyclobutenols under rhodium catalysis in detail. Herein, the author reports a rhodium-catalyzed ring-opening reaction of benzocyclobutenols, which shows a sharp contrast to those of the conventional ring-opening reactions, that is, by exclusive cleavage of the proximal C(sp\(^2\))–C(sp\(^3\)) bond.\(^13\) A new alkyne insertion reaction was also achieved based on this site-selective ring opening (Scheme 1).\(^14\)

**Scheme 1.** Ring opening of Benzocyclobutenols

**Results and Discussions**

Initially, ring opening of 1a was examined under various reaction conditions (Table 1). Simple heating of 1a in toluene at 100 °C selectively gave 2a in 86% yield (entry 1). Addition of a base accelerated the ring-opening reaction to yield only 2a again (entry 2). Irradiation with UV light (254 nm) also afforded 2a albeit in 30% yield along with a number of unidentified byproducts (entry 3). On the other hand, when 1a was heated at
100 °C in toluene in the presence of Rh(acac)(CH₂CH₂)₂ (5 mol %) and P(t-Bu)₃ (10 mol %), 12 2a and 3a were obtained as a mixture in 14% and 74% yield respectively (entry 4). Remarkably, 3a was obtained as a sole product in 89% yield when [Rh(OH)(cod)]₂ (2.5 mol %) was used in toluene without any additional ligand (entry 5). No 2-methylbenzophenone (2a) was detected in the reaction mixture even by GC analysis. The product selectivity was also dependent on a solvent and an additive. The reaction in dioxane under otherwise identical conditions afforded a mixture of 2a and 3a with a ratio of 21:79 (entry 6). The addition of 1,3-bis(2,6-dimethylphenyl)imidazole-2-ylidene (IPr) to [Rh(OH)(cod)]₂ yielded 2a without the formation of 3a (entry 7).

These results demonstrated possibility to switch the ring opening site completely from the distal C(sp³)−C(sp³) bond to the proximal C(sp²)−C(sp³) bond. The author proposes the following mechanistic explanation (Scheme 2). Initially, rhodium hydroxide deprotonates 1a to form rhodium(I) benzocyclobutenolate A. It is assumed that the arene moiety intramolecularly π-coordinates to the rhodium center, as is the case with Rh(PEt₃)₂(OCPh₃). 15 This coordination would assist the migration of the sp²
carbon onto the rhodium in preference to that of the sp\(^3\) carbon, thereby releasing the structural strain and forming a carbonyl group. The superior π-accepting character of the 1,5-cyclooctadiene ligand would facilitate the binding of the arene moiety. The generated arylrhodium species B undergoes protonation with 1a or H\(_2\)O to form the benzyl phenyl ketone (3a) together with regeneration of the rhodium alkoxide A. On the other hand, the ionic character of the rhodium benzocyclobutenolate is augmented in dioxane to partially cause anion-induced thermal ring opening. The strongly binding IPr ligand would occupy the fourth binding site of rhodium of A to discourage the π-coordination of the arene, thus suppressing the formation of 3a.

**Scheme 2.** Plausible mechanism

\[ \text{Scheme 2. Plausible mechanism} \]

Next, the author examined an alkyne insertion reaction by carrying out the rhodium-catalyzed ring opening of 1a in the presence of 3-hexyne (Scheme 3). The reaction mixture containing 3-hexyne was heated in toluene at 100 °C for 4 h to furnish dihydronaphthalene 5a in 85% yield. Mechanistically, the ring-opened arylrhodium(I) intermediate B undergoes not protonation but 1,2-addition across the carbon–carbon triple bond. The resulting alkenylrhodium(I) C adds back onto the carbonyl group in a 6-exo fashion. Alkoxyrhodium(I) D is then protonated to give dihydronaphthalene 5a with regeneration of rhodium benzocyclobutenolate A. Overall, the alkyne 4a is inserted into the proximal C(sp\(^2\))–C(sp\(^3\)) bond of 1a with site-selectivity to produce a formal [4 + 2] cycloadduct which is contrast markedly with that available through \(\sigma\)-quinodimethane intermediates.\(^8,9\)
Scheme 3. Rhodium-catalyzed reaction of 2a with 3-hexyne (4a)

\[
\text{Scheme 3. Rhodium-catalyzed reaction of 2a with 3-hexyne (4a)}
\]

The six-membered ring forming reaction proceeded successfully with various combinations of benzocyclobutenols 1 and alkynes 4 to demonstrate the generality of the unique site-selective insertion (Table 2). Even the ortho-substituted derivative 1d showed the same site-selectivity to give dihydronaphthalene 5d in 79% yield (entry 3). The presence of electron-donating methoxy and withdrawing trifluoromethyl groups on the benzene ring scarcely affected the reaction (entries 4 and 5). A chloro group remained intact (entry 6). High regioselectivities were observed with unsymmetrical alkynes bearing one aryl or vinyl substituent (entries 8 and 9), which was located at the β-position (next to the hydroxyl group) of the resulting dihydronaphthalene skeleton. On the other hand, the unsymmetrical dialkyl-substituted alkyne 4e gave a mixture of regioisomers with the ratio of 75:25 (entry 10). The regioselectivities observed with these unsymmetrical alkynes were similar to previous example in which \(o\)-carbonyl-substituted arylrhodium species intermolecularly added onto alkynes. An unprotected hydroxyl group and a pyridine moiety were allowed in the alkynes (entries 11 and 12). Insertion of terminal alkynes such as phenylethyn failed due to rapid self-oligomerization.

<sup>a</sup>Reaction conditions: benzocyclobutenol 1 (0.20 mmol), alkyne 4 (1.1 equiv), [Rh(OH)(cod)]<sub>2</sub> (2.5 mol %), toluene (1.0 mL), 100 °C, 4 h. <sup>b</sup>Isolated yields. Regioisomeric ratios in parentheses.

**Conclusions**

The author has shown that [Rh(OH)(cod)]<sub>2</sub> induces ring opening of benzocyclobutenols with site-selective cleavage of the proximal C(sp<sup>2</sup>)–C(sp<sup>3</sup>) bond. This site-selectivity is complementary to that of the conventional ring-opening reactions. A new alkyne insertion reaction constructing a dihydronaphthalene framework was developed based on the unique ring opening.
Experimental section

General. All reactions were carried out under an argon atmosphere in oven-dried glassware with standard Schlenk techniques. Photoreactions were conducted with Rayonet RPR-100. IR measurements were performed on a FTIR SHIMADZU DR-8000. \(^1\)H and \(^{13}\)C NMR spectra were recorded on a Varian Mercury-vx400 (\(^1\)H at 400.44 MHz and \(^{13}\)C at 100.69 MHz) spectrometer. NMR data were obtained in CDCl\(_3\), acetone-d\(_6\), C\(_6\)D\(_6\), and CD\(_3\)CN. Proton chemical shifts were referenced to the residual proton signal of the solvent at 7.26 ppm (CHCl\(_3\)), 2.09 ppm (acetone), 7.15 ppm (benzene), and 1.96 ppm (CH\(_3\)CN). Carbon chemical shifts were referenced to the carbon signal of the solvent at 77.0 ppm (CHCl\(_3\)), 205.87 ppm (acetone), 128.62 ppm (benzene), and 118.26 ppm (CH\(_3\)CN). High-resolution mass spectra were recorded on a Thermo Scientific Exactive (ESI) spectrometer. Flash column chromatography was performed with silica gel 60N (Kanto). Preparative thin-layer chromatography (PTLC) was performed on silica gel plates with PF254 indicator (Merck). Gel permeation chromatography (GPC) was carried out with a Japan Analytical Industry LC-908.

Materials. Toluene and 1,4-dioxane were distilled from sodium/benzophenone ketyl. Anhydrous THF and anhydrous CH\(_2\)Cl\(_2\) were purchased from Kanto Chemical Co. Distilled water was purchased from Nacalai Tesque. The following chemicals were synthesized according to the literature procedures; [Rh(OH)(cod)],\(^{17a}\) 1-phenylbenzocyclobutenol 1a,\(^{17b}\) \(\beta\)-trifluoroacetyltoluene A,\(^{17c}\) 1,4,6-trimethyl-benzocyclobutenol 1d,\(^{17d}\) 4-methoxybenzocyclobutenol B,\(^{17e}\) 6-trifluoromethyl-1-phenylbenzocyclobutone,\(^{17f}\) and 6-chlorobenzocyclobutenone.\(^{17g}\) All other chemicals were available from commercial sources and were used as received without further purification.

Procedures for the ring-opening reaction of benzocyclobutenol 1a (Table 1)

Thermal reaction (entry 1)

A solution of benzocyclobutenol 1a (39.2 mg, 0.20 mmol) in toluene (1 mL) was stirred at 100 °C for 15 h. After the reaction mixture was cooled to room temperature, concentrated under reduced pressure. The residue was purified by preparative thin-layer
chromatography (hexane/ethyl acetate = 10/1) to give 2-methylbenzophenone 2a (33.7 mg, 0.17 mmol, 86%).

**Basic condition (entry 2)**

A solution of benzocyclobutenol 1a (39.2 mg, 0.20 mmol), sodium hydroxide (4.0 mg, 0.10 mmol, 0.50 equiv), and distilled water (10 µL) in dioxane (1 mL) was stirred at room temperature for 12 h. Then, water was added to the reaction mixture. The resulting aqueous solution was extracted with ethyl acetate (3 x 4 mL). The combined extracts were washed with H₂O and brine and dried over MgSO₄. The solvent removed by reduced pressure and the residue was purified by preparative thin-layer chromatography (hexane/ethyl acetate = 10/1) to give 2-methylbenzophenone 2a (34.1 mg, 0.17 mmol, 87%).

**Photoreaction (entry 3)**

After a solution of benzocyclobutenol 1a (39.2 mg, 0.20 mmol) in benzene (5 mL) was irradiated for 12 h with UV light (λ = 254 nm), the solvent was removed under reduced pressure to give 2-methylbenzophenone 2a (30%, NMR yield).

**Rhodium-catalyzed reaction (entry 4)**

A solution of Rh(acac)(CH₂CH₂)₂ (2.6 mg, 10 µmol, 5.0 mol %) and P(t-Bu)₃ (4.0 mg, 20 µmol, 10 mol %) in toluene (1 mL) was stirred at 100 °C for 2 h. The reaction mixture was added to benzocyclobutenol 1a (39.2 mg, 0.20 mmol, 1.0 equiv) and the solution was stirred at 100 °C for 24 h. After cooled to room temperature, the reaction mixture was passed through a pad of Florisil® with ethyl acetate as the eluent. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography (hexane/ethyl acetate = 10/1) to give 2-methylbenzophenone 2a (5.5 mg, 0.028 mmol, 14%) and benzyl phenyl ketone 3a (29.0 mg, 0.15 mmol, 74%).

**Rhodium-catalyzed reaction (entry 5)**

A solution of [Rh(OH)(cod)]₂ (2.3 mg, 5.0 µmol, 2.5 mol %) and benzocyclobutenol 1a (39.2 mg, 0.20 mmol, 1.0 equiv) in toluene (1 mL) was stirred at 100 °C for 1 h. After cooled to room temperature, the reaction mixture was passed through a pad of Florisil® with ethyl acetate as the eluent. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography
(hexane/ethyl acetate = 10/1) to give benzyl phenyl ketone 3a (34.9 mg, 0.18 mmol, 89%).

**Rhodium-catalyzed reaction (entry 6)**

A solution of [Rh(OH)(cod)]$_2$ (2.2 mg, 5.0 µmol, 2.5 mol %) and benzocyclobutenol 1a (39.2 mg, 0.20 mmol, 1.0 equiv) in dioxane (1 mL) was stirred at 100 °C for 3 h. After cooled to room temperature, the reaction mixture was passed through a pad of Florisil® with ethyl acetate as the eluent. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography (hexane/ethyl acetate = 20/1) to give 2-methylbenzophenone 2a (7.9 mg, 0.040 mmol, 20%) and benzyl phenyl ketone 3a (29.1 mg, 0.15 mmol, 74%).

**Rhodium-catalyzed reaction (entry 7)**

A solution of [Rh(OH)(cod)]$_2$ (2.3 mg, 5.0 µmol, 2.5 mol %) and IPr (10.2 mg, 10 mmol, 12 mol %) in toluene (1.0 mL) was stirred at room temperature for 4 h. The reaction mixture was added to benzocyclobutenol 1a (39.0 mg, 0.20 mmol, 1.0 equiv) in toluene (1 mL) was stirred at 100 °C for 15 h. After cooled to room temperature, the reaction mixture was passed through a pad of Florisil® with ethyl acetate as the eluent. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography (hexane/ethyl acetate = 10/1) to give benzyl phenyl ketone 3a (31.7 mg, 0.16 mmol, 80%).

**A procedure for the synthesis of 1c**

![Diagram](image-url)

A solution of o-trifluoroacetyltoluene A (39 mg, 0.20 mmol) in benzene (1 mL) was irradiated for 6 h with UV light (λ = 300 nm). After complete conversion of A, the solvent was removed under reduced pressure to give a quantitative yield of benzocyclobutenol 1c as colorless oil; IR (ATR): 3349, 1331, 1153, 1016, 756 cm$^{-1}$; $^1$H NMR (400 MHz, C$_6$D$_6$): $\delta = 2.34$ (br s, 1H), 2.76 (dd, $J = 14.4, 0.8$ Hz, 1H), 3.39 (d, $J = 14.4$ Hz, 1H), 6.75–6.78 (m, 1H), 6.90–7.04 (m, 3H); $^{13}$C NMR (100 MHz, C$_6$D$_6$): $\delta =$ 42.4, 78.9 (q, $J = 32.3$ Hz), 122.7, 124.2, 126.1 (q, $J = 279.6$ Hz), 128.8, 131.7, 142.6,
A procedure for the synthesis of benzocyclobutenol 1e

To a solution of oxalyl chloride (1.4 g, 11 mmol, 1.1 equiv) in CH$_2$Cl$_2$ (5 mL), dimethyl sulfoxide (1.6 mL, 22 mmol, 2.2 equiv) was added dropwise at –78 ºC. After the reaction mixture was stirred at this temperature for 1 h, a solution of 4-methoxybenzocyclobutenol B (1.5 g, 10 mmol) in CH$_2$Cl$_2$ (5 mL) was added dropwise. Additional stirring at –78 ºC for 1 h, Et$_3$N (3.1 mL, 22 mmol, 2.2 equiv) was added dropwise and the reaction mixture was stirred at 0 ºC for 1 h. The resulting mixture was quenched with water (10 mL) and extracted with CH$_2$Cl$_2$ (3 x 5 mL). The combined extracts were washed with H$_2$O and brine and dried over MgSO$_4$. The solvent removed by reduced pressure and the residue was purified by column chromatography (hexane/ethyl acetate = 10/1) to give C (1.3 g, 8.9 mmol, 89%).

To a solution of C (740 mg, 5.0 mmol) in THF (10 mL), a solution of PhLi in cyclohexane-diethylether (1.07 M, 5.1 mL, 5.5 mmol) was added dropwise at –78 ºC. After stirred at this temperature for 30 min, the reaction mixture was warmed to room temperature. The resulting mixture was quenched by addition of a saturated NH$_4$Cl solution and the aqueous solution was extracted with ethyl acetate. The combined extracts were washed with H$_2$O and brine and dried over Na$_2$SO$_4$. The solvent removed by reduced pressure. The residue was purified by column chromatography (hexane/ethyl acetate = 5/1) to give benzocyclobutenol 1e as colorless oil (740 mg, 3.3 mmol, 66%); IR (ATR): 3396, 2924, 1587, 1475, 1273, 1072, 698 cm$^{-1}$; $^1$H NMR (400 MHz, CDCl$_3$): $\delta$ = 2.68 (s, 1H), 3.52 (d, $J$ = 14.0 Hz, 1H), 3.58 (d, $J$ = 14.0 Hz, 1H), 3.82 (s, 3H), 6.81 (s, 1H), 6.85–6.88 (m, 1H), 7.20 (d, $J$ = 8.4 Hz, 1H), 7.28–7.30 (m, 1H), 7.32–7.36 (m, 2H), 7.46–7.49 (m, 2H); $^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ = 49.2, 55.4, 80.5, 109.3, 114.5, 122.9, 125.6, 127.2, 128.1, 140.9, 143.0, 143.8, 161.1; HRMS (ESI): Calcd for C$_{15}$H$_{14}$O$_2$, [M+H]$^+$ 227.1067. Found m/z 227.106.
1f:

According to the procedure analogous to that described for 1e, 1f (1.2 g, 4.6 mmol, 91\%) was prepared from 6-trifluoromethyl-1-phenylbenzocyclobutenone (930 mg, 5.0 mmol). Purified by column chromatography (hexane/ethyl acetate = 5/1) as colorless oil; IR (ATR): 3420, 3061, 1616, 1448, 1323, 1119, 696 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ = 2.95 (s, 1H), 3.56 (d, J = 14.4 Hz, 1H), 3.67 (d, J = 14.0 Hz, 1H), 7.28–7.54 (m, 8H); ¹³C NMR (100 MHz, acetone-d₆): δ = 51.6, 81.2, 124.0 (q, J = 270.2 Hz), 124.4 (q, J = 34.4 Hz), 124.6 (q, J = 4.4 Hz), 125.2, 127.3, 128.2, 128.4, 130.3, 144.1, 144.7, 148.8; HRMS (ESI): Calcd for C₁₅H₁₅F₃ON, [M+NH₄]⁺ 282.1100. Found m/z 282.1093.

1g:

According to the procedure analogous to that described for 1e, 1g (970 mg, 4.2 mmol, 83\%) was prepared from 6-chloro-1-phenylbenzocyclobutenone (760 mg, 5.0 mmol). Purified by column chromatography (hexane/ethyl acetate = 5/1) as colorless oil; IR (ATR): 3362, 2928, 1585, 1448, 1134, 758, 696 cm⁻¹; ¹H NMR (400 MHz, CDCl₃): δ = 2.84 (br s, 1H), 3.55 (d, J = 14.0 Hz, 1H), 3.59 (d, J = 14.4 Hz, 1H), 7.14 (dd, J = 7.2, 0.8 Hz, 1H), 7.25–7.40 (m, 5H), 7.50–7.53 (m, 2H); ¹³C NMR (100 MHz, CDCl₃): δ = 49.5, 81.4, 122.3, 125.5, 126.8, 127.78, 127.80, 128.4, 131.1, 142.5, 144.2, 145.1; HRMS (ESI): Calcd for C₁₄H₁₁ClONa, [M+Na]⁺ 253.0391. Found m/z 253.0387.

Rhodium-catalyzed reaction of 1a and 4a

To an oven-dried flask equipped with a stirrer bar was added [Rh(OH)(cod)]₂ (2.3 mg, 5.0 µmol, 2.5 mol %). The flask was capped with a rubber septum, evacuated and
refilled with argon three times. Then, a solution of 1-phenylbenzocyclobutenol 1a (39 mg, 0.20 mmol, 1.0 equiv) and 3-hexyne (18 mg, 0.22 mmol, 1.1 equiv) in dry toluene (1 mL) was added by syringe. After stirred at 100 °C for 4 h, the reaction mixture was cooled to room temperature. The resulting mixture was passed through a pad of Florisil® and eluted with ethyl acetate. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography (hexane/ethyl acetate = 5/1) to give dihydronaphthalene 5a as colorless oil (47 mg, 0.17 mmol, 84%); IR (ATR): 3460, 2964, 1726, 1447, 1240, 1038, 766, 700 cm⁻¹; ¹H NMR (400 MHz, acetone-d₆): δ = 1.10 (t, J = 7.2 Hz, 3H), 1.26 (t, J = 7.6 Hz, 3H), 2.21–2.30 (m, 1H), 2.44–2.53 (m, 1H), 2.66–2.81 (m, 2H), 3.11 (d, J = 15.2 Hz, 1H), 3.37 (d, J = 15.2 Hz, 1H), 4.33 (s, 1H), 6.96 (d, J = 7.2 Hz, 1H), 7.01–7.05 (m, 1H), 7.13–7.24 (m, 4H), 7.40–7.45 (m, 3H); ¹³C NMR (100 MHz, acetone-d₆): δ = 14.2, 15.0, 21.6, 22.0, 47.3, 76.7, 123.4, 126.4, 126.6, 127.11, 127.14, 128.1, 128.3, 134.2, 134.8, 135.6, 143.0, 146.3; HRMS (ESI): Calcd for C₂₀H₂₁O, [M–H]– 277.1598. Found m/z 277.1603.

5b:

![Structure of 5b]

Purified by preparative thin-layer chromatography (hexane/ethyl acetate = 5/1) as colorless oil; IR (ATR): 3477, 2964, 1441, 1373, 1059, 874, 743 cm⁻¹; ¹H NMR (400 MHz, acetone-d₆): δ = 1.11–1.14 (m, 6H), 1.21 (t, J = 7.2 Hz, 3H), 2.40–2.64 (m, 4H), 2.75 (d, J = 14.8 Hz, 1H), 3.04 (d, J = 14.8 Hz, 1H), 3.71 (s, 1H), 7.08–7.16 (m, 2H), 7.20–7.24 (m, 1H), 7.32 (d, J = 8.0 Hz, 1H); ¹³C NMR (100 MHz, acetone-d₆): δ = 14.2, 15.4, 20.7, 21.4, 25.8, 45.8, 72.6, 123.4, 126.2, 127.0, 128.4, 131.2, 135.3, 136.0, 145.6; HRMS (ESI): Calcd for C₁₅H₂₁O, [M+H]⁺ 217.1587. benzocyclobutenones has been reported: Xu, T.; Dong, G. *Angew. Chem., Int. Ed.* 2012, 51, 7567.

Chapter 3

Construction of Tetralin Skeletons Based on
Rhodium-Catalyzed Site-Selective Ring Opening of Benzocyclobutenols

Abstract
An intermolecular reaction of benzocyclobutenols with electron-deficient alkenes provided tetrahydronaphthalene skeletons in the presence of a rhodium catalyst. A double bond of alkene was inserted into the proximal C(sp$^2$)–C(sp$^3$) bond selectively. The produced structures made a remarkable contrast with those synthesized from the identical starting materials under thermal reaction conditions.
**Introduction**

Tetralin is a key structural scaffold found in a wide variety of biologically active substances including natural products such as heritonine,\(^1\) cycloolivil,\(^2\) morphine,\(^3\) and daunorubicin.\(^4\) Much attention has been paid to develop synthetic strategy leading to tetralin skeletons. Herein is disclosed a new method to access tetralin derivatives from benzocyclobutenols based on their site-selective ring opening with the aid of a rhodium catalyst.\(^5\)–\(^8\) 2-Hydroxytetralins are stereoselectively synthesized by an insertion reaction of vinyl ketones into the C(sp\(^2\))–C(sp\(^3\)) bond of benzocyclobutenols. 2-Tetralones were also synthesized from 1-alkenylbenzocyclobutenols under the catalysis of rhodium. The produced structures make a remarkable contrast with those available from the identical starting materials under thermal reaction conditions.

A [4 + 2] cycloaddition reaction of \(o\)-quinodimethanes with alkenes presents one of the most reliable synthetic pathways to construct tetralin skeletons.\(^9\) For example, thermal reaction of benzocyclobutenols generates hydroxyl-substituted \(o\)-quinodimethanes\(^{10}\), which undergo regioselective [4 + 2] cycloaddition reaction with electron-deficient alkenes in an endo fashion.\(^{11}\) It has also been known that treatment of benzocyclobutenols with butyllithium generates an oxyanion intermediate, which is an analogous pathway to form tetralin skeletons even at \(-78\) °C.\(^{12}\) In these cases, the C–C double bond is formally inserted into the C(sp\(^2\))–C(sp\(^3\)) bond of the cyclobutene ring.

On the other hand, the author has shown a different type of ring opening reaction of benzocyclobutenols in chapter 2; a rhodium complex prompts the cleavage of the C(sp\(^2\))–C(sp\(^3\)) bond to generate an \(o\)-acylmethyl-substituted arylrhodium intermediate.\(^5,^{13,14}\) The subsequent intermolecular addition across the C–C triple bond of alkynes generates alkenylrhodium species, followed by intramolecular addition onto the carbonyl group to construct dihydronaphthalene frameworks. In a formal sense, a C–C triple bond is inserted into the C(sp\(^2\))–C(sp\(^3\)) bond of the cyclobutene ring in an atomeconomical manner. This outcome led the author to explore new synthetic pathways leading to tetrains (tetrahydronaphthalenes) from benzocyclobutenol derivatives.

**Results and Discussions**

The author first carried out a thermal reaction of 1a and 2a at 100 °C for 30 min in the absence of a rhodium catalyst (Scheme 1a). The thermal ring opening reaction of 1a was so slow that 90% of 1a was recovered. Next tried was the reaction of 1a and 2a in
the presence of \([\text{Rh(OH)(nbd)}]_2\) under otherwise identical conditions. The C–C double bond of 2a was successfully inserted into the C(sp\(^2\))–C(sp\(^3\)) bond of 1a to produce 2-hydroxytetralin 4a in 82\% yield with a trace amount of the minor diastereomer (diastereomeric ratio, dr = 15:1) (Scheme 1b).

**Scheme 1.** Thermal reaction vs. Rhodium-catalyzed reaction

(a) Thermal reaction

\[
\begin{align*}
\text{toluene, 130 °C, 12 h} & \\
\text{1a} + \text{2} & \rightarrow \text{3} \\
& \text{60\%, dr > 20:1}
\end{align*}
\]

(b) Rhodium-catalyzed reaction

\[
\begin{align*}
\text{toluene, 100 °C, 0.5 h} & \\
\text{1a} + \text{2a} & \rightarrow \text{4a} \\
& \text{82\%, dr = 15:1}
\end{align*}
\]

A feasible mechanistic scenario for the diastereoselective formation of 4a is depicted in Scheme 2. Initially, the hydroxylic proton of benzocyclobutenol 1a is exchanged with rhodium to furnish the rhodium benzocyclobutenolate A. The benzene ring \(\pi\)-coordinates to the rhodium center.\(^{15}\) This \(\pi\)-coordination is retained during the subsequent \(\beta\)-carbon elimination so that the ipso carbon selectively migrates onto rhodium. Thus, the C(sp\(^2\))–C(sp\(^3\)) bond is selectively cleaved. The resulting arylrhodium species B undergoes conjugate addition across 2a, which is taking an \(s\)-\(cis\) conformation to allow a six-membered transition state. As a consequence, the (Z)-enolate C is generated. Then, an intramolecular aldol reaction takes place again via a six-membered transition state, for which chair-like transition state is assumed, to afford syn-aldolate D with stereoselectivity.\(^{16,17}\) Protonation of D with water, generated in the first step, or with 1a produces 4a and the next catalytic cycle restarts.
Scheme 2. Proposed mechanism for the formation of 4a

The scope of the site-selective insertion reaction is shown in Table 1. Although non-substituted benzocyclobutenol (R = H) failed to afford the 2-hydroxytetralin, substituted benzocyclobutenols reacted with vinyl ketones to afford 4b–g with dr ranging from 8:1 to >20:1. Cyclopropyl, methoxy and chloro groups remained intact under the reaction conditions. The site-selective ring opening was observed even when the migrating ipso carbon was hindered due to its ortho-isopropyl group. Phenyl vinyl ketone was also successfully engaged in the insertion reaction. On the other hand, alkenes lacking electron-withdrawing groups (e.g. ethylene and styrene) were not applicable for this reaction. α,β-Unsaturated ketones possessing a substituent at the α- or β-position gave significantly lower yield, presumably due to steric reasons. The use of acrolein and acrylate gave a complex mixture containing the desired 2-hydroxytetralin (<30% yield).
Next examined was the construction of tetralones from 1-alkenylbenzocyclobutenol 5a, which was easily prepared by addition of alkenyllithium to benzocyclobutene. When 5a was simply heated at 80 °C in $\text{C}_6\text{D}_6$ for 4.5 h, 1-tetralone 6a was obtained in 91% yield, as previously reported for analogous substrates (Scheme 3a). 18

4π-Electrocyclic ring opening of 5a is followed by 6π-electrocyclic ring closure to afford 6a. In sharp contrast, treatment of 5a with a catalytic amount of [Rh(OH)(cod)]$_2$ at 40 °C for 2 h gave 2-tetralone 7a in 83% isolated yield. 19 Mechanistically, it is assumed that the site-selective cleavage of the C(sp$^2$)–C(sp$^3$) bond generates the arylrhodium intermediate F with the ortho position substituted by an $\alpha,\beta$-unsaturated carbonyl group. An intramolecular conjugate addition reaction occurs and the resulting oxa-π-allylrhodium G is protonated with water, or with 5a to give 7a (Scheme 3b).
Scheme 3. Thermal reaction vs. Rhodium-catalyzed reaction

(a) Thermal reaction

\[
\begin{align*}
\text{5a} & \xrightarrow{\text{C}_{6}D_{6}, 80^\circ C, 4.5 \text{ h}} \text{6a} \\
& \text{91%}
\end{align*}
\]

(b) Rhodium-catalyzed reaction

Thus, a rhodium complex also changes the pathway of the intramolecular rearrangement reaction of 5a. In addition, the racemic mixture of 5a was enantioselectively rearranged when electron-deficient chiral diphosphine (R)-MeO-F_{12}-BIPHEP\(^{20}\) was employed as the ligand for rhodium. 2-Tetralone 7a was obtained in 72% yield with the enantiomeric ratio (er) of 91:9. This reaction condition was applied to the synthesis of 7b (er = 84:16) and 7c (er = 99:1) (Scheme 4).

Scheme 4. Asymmetric rearrangement of 5

\[
\begin{align*}
\text{5} & \xrightarrow{\text{toluene, 50^\circ C, 10 h}} \text{7} \\

Conclusions

Tetralin skeletons are constructed from benzocyclobutenols based on the rhodium-catalyzed site-selective ring opening reaction. Vinyl ketones are site-selectively inserted into the C(sp\(^2\))–C(sp\(^3\)) bond of benzocyclobutenols to produce 2-hydroxytetralins. 1-Alkenylbenzocyclobutenols are restructured into 2-tetralones via intramolecular conjugate addition. The obtained tetralins markedly contrast with those given by the conventional thermal reactions.
Experimental section

General. All reactions were carried out under an argon atmosphere in an oven-dried glassware with standard Schlenk techniques. Photoreactions were conducted with Rayonet RPR-100. IR measurements were performed on a FTIR SHIMADZU DR-8000. $^1$H and $^{13}$C NMR spectra were recorded on a Varian Mercury-vx400 ($^1$H at 400.44 MHz and $^{13}$C at 100.69 MHz) and JEOL JNM-ECA600 ($^1$H at 600.17 MHz) spectrometer. NMR data were obtained in CDCl$_3$ or C$_6$D$_6$. Proton chemical shifts were referenced to the residual proton signal of the solvent at 7.26 ppm (CHCl$_3$), 7.16 ppm (C$_6$H$_6$). Carbon chemical shifts were referenced to the carbon signal of the solvent at 77.0 ppm (CDCl$_3$) and 128.62 ppm (C$_6$D$_6$). High-resolution mass spectra were recorded on a Thermo Scientific Exactive (ESI, APCI, EI). Flash column chromatography was performed with silica gel 60N (Kanto). Preparative thin-layer chromatography (PTLC) was performed on silica gel plates with PF254 indicator (Merck). HPLC analysis was performed by 4.6×250 mm column. Gel permeation chromatography was carried out with a Japan Analytical Industry LC-908.

Materials. Toluene was distilled over sodium/benzophenone ketyl. [Rh(OH)(cod)]$_2$, [Rh(OH)(nb)]$_2$, benzocyclobutenol 1a, benzocyclobutenol 1d, benzocyclobutenol 1e, benzocyclobutenol 1f, and (E)-1-ido-1-octene were prepared according to the literature procedures. All other chemicals were available from commercial sources and were used as received without further purification.

A procedure for the synthesis of benzocyclobutenols (1b, 1c)

![chemical structure of benzocyclobutenone A](image)

To a solution of benzocyclobutenone A (354 mg, 3.0 mmol) in THF (10 mL), a solution of $i$-PrMgBr in THF (3.0 M, 2.5 mL, 0.84 mmol) was added dropwise at 0 °C. Then, the reaction mixture was warmed to room temperature. The resulting mixture was quenched by addition of a saturated NH$_4$Cl solution and the aqueous solution was extracted with ethyl acetate. The combined organic layer was washed with H$_2$O and brine, and then was dried over Na$_2$SO$_4$. The solvent was removed by reduced pressure. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 5/1) and gel permeation chromatography to give benzocyclobutenol 1b (203 mg, 1.3
mmol, 42%) as colorless oil; IR (ATR): 3383, 2961, 1456, 1364, 752, 716 cm\(^{-1}\); \(^1\)H NMR (400 MHz, CDCl\(_3\)): \(\delta = 1.04\) (d, \(J = 6.8\) Hz, 3H), 1.09 (d, \(J = 7.2\) Hz, 3H), 1.82–2.08 (m, 2H), 3.06 (d, \(J = 14.4\) Hz, 1H), 3.39 (d, \(J = 14.0\) Hz, 1H), 7.15–7.30 (m, 4H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)): \(\delta = 17.2, 17.3, 35.3, 44.9, 83.9, 121.5, 123.8, 126.9, 129.1, 141.9, 149.8\); HRMS (APCI): Calcd for C\(_{11}\)H\(_{15}\)O, [M+H]\(^+\) 163.1117. Found m/z 163.1115.

1c:

According to the procedure analogous to that described for 1b, 1c (81 mg, 0.5 mmol, 24%) was prepared from benzocyclobutenone (244 mg, 2.1 mmol). Purified by gel permeation chromatography after column chromatography on silica gel (hexane/ethyl acetate = 3/1) afforded 1c as white solid; IR (ATR): 3207, 3007, 1456, 1352 cm\(^{-1}\); \(^1\)H NMR (400 MHz, CDCl\(_3\)): \(\delta = -0.02–0.04\) (m, 1H), 0.43–0.61 (m, 3H), 1.41–1.48 (m, 1H), 2.06 (s, 1H), 3.19 (d, \(J = 14.0\) Hz, 1H), 3.39 (d, \(J = 14.0\) Hz, 1H), 7.08–7.29 (m, 4H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)): \(\delta = 9.1, 31.8, 46.4, 81.4, 121.1, 123.9, 127.1, 129.2, 141.5, 150.2\); HRMS (APCI): Calcd for C\(_{11}\)H\(_{13}\)O, [M+H]\(^+\) 161.0961. Found m/z 161.0959.

A procedure for the synthesis of 1-alkenylbenzocyclobutenols (5a, 5b, 5c)

To a solution of (\(E\))-1-iodo-1-octene (7.14 g, 30 mmol) in Et\(_2\)O (40 mL), t-BuLi (1.67 M, 37.5 mL, 60 mmol) was added dropwise at –78 °C. After 0.5 h, the reaction mixture was warmed to room temperature for 1 h. The reaction mixture was cooled to –78 °C. Then, benzocyclobutenone (3.54 g, 30 mmol) was added dropwise. After 1 h, the resulting mixture was quenched by addition of HCl (2.0 M) at –78 °C and the aqueous solution was extracted with Et\(_2\)O. The combined organic layer was washed with a saturated Na\(_2\)S\(_2\)O\(_3\) solution and brine, and then was dried over Na\(_2\)SO\(_4\). The solvent was removed by reduced pressure. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 10/1) and gel permeation chromatography to give benzocyclobutenol 5a (3.7 g, 16 mmol, 54%) as colorless oil; IR (ATR): 3321, 2922,
2853, 1456 cm\(^{-1}\); \(^1\)H NMR (400 MHz, CDCl\(_3\)): \(\delta = 0.87\) (t, \(J = 6.8\) Hz, 3H), 1.21–1.39 (m, 8H), 2.00–2.13 (m, 2H), 2.30 (s, 1H), 3.31 (d, \(J = 14.4\) Hz, 1H), 3.45 (d, \(J = 14.0\) Hz, 1H), 5.78 (dt, \(J = 15.2, 6.4\) Hz, 1H), 5.87 (d, \(J = 15.6\) Hz, 1H), 7.17–7.32 (m, 4H); \(^{13}\)C NMR (100 MHz, CDCl\(_3\)): \(\delta = 14.1, 22.6, 28.9, 29.1, 31.7, 32.1, 48.1, 80.1, 121.3, 124.1, 127.3, 129.4, 130.7, 131.6, 141.7, 149.1\); HRMS (EI): Calcd for C\(_{16}\)H\(_{23}\)O, [M+H]\(^+\) 231.1743. A typical procedure for rhodium-catalyzed reactions

To an oven-dried flask equipped with a stirrer bar were added [Rh(OH)(nbd)]₂ (5.0 µmol, 2.5 mol %) and benzocyclobutenol 1a (39.3 mg, 0.20 mmol, 1.0 equiv). The flask was capped with a rubber septum, evacuated and refilled with argon three times. Then, a solution of methyl vinyl ketone 2a (32.6 µL, 0.40 mmol, 2.0 equiv) in dry toluene (1 mL) was added by syringe. After being stirred at 100 °C for 30 min, the reaction mixture was cooled to room temperature. The resulting mixture was passed through a pad of Florisil® and eluted with ethyl acetate. The filtrate was concentrated under reduced pressure. The residue was purified by preparative thin-layer chromatography on
silica gel (hexane/ethyl acetate = 7/1) to give tetralin 4a as yellow solid (43.5 mg, 0.16 mmol, 82%); IR (ATR): 3474, 1695, 1167, 1067 cm$^{-1}$; $^1$H NMR (600 MHz, CDCl$_3$): $\delta$ = 2.04 (s, 3H), 3.00–3.05 (m, 2H), 3.17 (d, $J$ = 17.4 Hz, 1H), 3.27 (dd, $J$ = 16.2, 12.6 Hz, 1H), 3.65 (dd, $J$ = 12.6, 4.8 Hz, 1H), 4.21 (d, $J$ = 2.4 Hz, 1H), 7.07–7.08 (m, 1H), 7.16–7.17 (m, 3H), 7.27 (t, $J$ = 7.8 Hz, 1H), 7.36–7.39 (m, 2H), 7.50–7.52 (m, 2H); $^{13}$C NMR (100 MHz, CDCl$_3$): $\delta$ = 30.0, 31.8, 44.2, 53.3, 73.7, 124.7, 126.0, 126.4, 127.1, 128.2, 128.5, 129.2, 133.3, 134.0, 146.8, 214.7; HRMS (APCI): Calcd for C$_{18}$H$_{19}$O$_2$, [M+H]$^+$ 267.1380. Stereospecific Construction of Planar Chirality through Carbon–Carbon Bond Cleavage

Abstract
A tricyclic benzocyclobutenol with central chirality was reacted with methyl vinyl ketone in the presence of a rhodium catalyst. The cyclobutene ring was opened by β-carbon elimination and the resulting arylrhodium species underwent conjugate addition to methyl vinyl ketone leading to a metacyclophane with planar chirality. In this reaction, central chirality is transferred to planar chirality in a stereospecific manner during the process of the carbon–carbon bond cleavage by β-carbon elimination.
Introduction

Metacyclophanes are cyclic compounds possessing a central arene moiety of which 1,3-positions are bridged with an ansa chain.\(^1\) The arene ring can rapidly flip in many cases, but when the flipping is restricted, metacyclophanes can exhibit stable planar chirality. Such an intriguing chiral metacyclophane unit can be observed in variable natural products like galeon and vancomycin.\(^2\) Chiral metacyclophanes also constitute a key structural element of some pharmaceuticals\(^3\) and supramolecular host materials that capture small molecules\(^4\). Consequently, the development of methods to access chiral metacyclophane skeletons stereoselectively has attracted much attention.\(^5\)-\(^7\)

The author herein discloses a sequential process to expand orthocyclophanes 1 into their more strained constitutional isomers, metacyclophanes 2 (Scheme 1). In this transformation, unstrained C–H and C–C bonds are cleaved and exchanged in a formal sense. Of note is that the whole transformation is energetically uphill (vide infra) and atom-economical. The overall driving force ultimately derives from light. The process can also be extended to the stereoselective synthesis of metacyclophanes 4 with planar chirality.

Scheme 1. Ring expansion reactions

Results and Discussions

Initially, a THF solution of orthocyclophane 1a (0.02 M) in a Pyrex tube was irradiated with UV light (270–350 nm) for 13 h (Scheme 2). Photocyclization\(^8\) took place to afford benzocyclobutenol (±)-5a in 92% isolated yield. Subsequently, the benzocyclobutenol (±)-5a was treated with a catalytic amount of [Rh(OH)(cod)]\(_2\) at 60 °C in MeOH for 5 h. The benzocyclobutene ring was opened with site-selective
cleavage of the C(sp²)–C(sp³) bond to afford [9]metacyclophane 2a in 72% isolated yield. The 1H NMR of 2a shows only one singlet peak for the benzylic protons of the ansa chain (δ = 3.67 (s, 2H)), suggesting that the benzene ring rotates up and down freely across the ansa chain.

Scheme 2. Ring expansion 1a to 2a

A two-step mechanistic scenario is depicted in Scheme 3. The first step is a photo-induced ring closing reaction (Scheme 3a). According to the mechanism originally proposed by Wagner et al., the ketone 1a is electronically excited and the excited carbonyl group behaves as an oxyl radical to site-specifically abstract the benzylic hydrogen. The resulting 1,4-biradical species Aa, possessing an o-phenylene linker, spontaneously furnishes an isomeric mixture of the o-quinodimethanes (E)- and (Z)-Ba. The (Z)-isomer having an outward-oriented hydroxy group undergoes a 4π-electrocyclic ring closure reaction to form benzocyclobutenol (±)-5a. On the other hand, the (E)-isomer having an inward-oriented hydroxy group undergoes facile 1,5-hydrogen shift to regenerate 1a rather than the ring closure.

The second step is a ring-opening reaction promoted by the rhodium hydroxide complex (Scheme 3b). The hydroxyl group of (±)-5a is replaced with the rhodium hydroxide to generate rhodium benzocyclobutenolate Ca, in which the benzene ring likely π-coordinates to rhodium. Next is followed by β-carbon elimination, for which the π-coordination facilitates site-selective cleavage of the C(sp²)–C(sp³) bond to furnish arylrhodium Da. Finally, protonation yields [9]metacyclophane 2a. In order to evaluate the thermodynamics of this sequential process, DFT calculations were performed at the B3LYP/6-31 G(d) level (Gas phase at 1 atm, 298 K) (Experimental section Fig. 1). The results suggest that (±)-5a and 2a are thermodynamically less stable than 1a by ca. 32.3 and 3.8 kcal/mol, respectively. The irreversible formation of highly energetic intermediate (±)-5a by the first photocyclization process enables to proceed the energetically uphill transformation from the reactant 1a to its more strained constitutional isomer 2a.
Scheme 3. Plausible mechanisms for the formation of 2a

(a) 1st step

The author also succeeded in the transformation of orthocyclophane 1a to metacyclophane 2a in one flask. The methanol solution of orthocyclophane 1a was irradiated with UV light at room temperature for 24 h, followed by the addition of a rhodium catalyst directly to the reaction mixture without the isolation of benzocyclobutenol (±)-5a. Metacyclophane 2a was obtained in 63% isolated yield (Scheme 4).

Scheme 4. Synthesis of metacyclophane in one flask
Next tried was utilizing the arylrhodium intermediate D for the subsequent C–C bond formation, aiming at the synthesis of planar chiral metacyclophanes. The racemic benzocyclobutenol (±)-5a was treated with a rhodium catalyst in the presence of methyl vinyl ketone 3 (10 equiv) in toluene at room temperature for 10 h (Scheme 5). The reaction furnished [9]metacyclophane 4a (69% isolated yield) that successfully incorporated 3 at the arene carbon between the 1,3-ansa chain. The ^1H NMR of 4a shows the two distinctly coupled doublets at δ = 3.44 (d, J = 14.6 Hz, 1 H) and δ = 3.95 (d, J = 14.6 Hz, 1 H), indicating the inequivalency of the two benzylic protons of the ansa chain. The chiral HPLC analysis of the 4a exhibited two peaks of equal intensities in consistence with a racemic mixture of two enantiomers. The author assumes that the substituent derived from methyl vinyl ketone prohibits the flipping of the benzene ring to construct stable planar chirality.

Scheme 5. Planar chiral derivatives

The interest was directed to the transition of stereochemistry through the ring opening/addition process, during which central chirality of benzocyclobutenol 5a disappeared and planar chirality of 4a was generated. The racemic mixture of benzocyclobutenol (±)-5a was successfully separated by preparative chiral HPLC to the two enantiomers (+)- and (−)-5a. The reaction of (+)-5a (>99:1 enantiomeric ratio (er)) with 3 in the presence of the achiral [Rh(OH)(cod)]_2 catalyst afforded (+)-4a in 72% yield (Scheme 6). A chiral HPLC analysis showed that the enantiomeric purity was retained (>99:1 er). This result indicated the stereochemical integrity during the transfer of central chirality of 5a to planar chirality of 4a, letting the author examine the stereospecificity of chiral transfer in more detail.

Scheme 6. Enantiopure starting material
The ring expansion of orthocyclophane 1b to metacyclophane (±)-4b was carried out (Scheme 7). The first photocyclization of 1b afforded benzocyclobutenol (±)-5b in 78% isolated yield as a single diastereomer. It was determined by NOE analysis that the hydroxy group was trans to the (trimethylsilyl)methyl substituent. Subsequent treatment of (±)-5b with the rhodium catalyst in the presence of 3 (10 equiv) in toluene at room temperature for 24 h furnished [9]metacyclophane (±)-4b in 62% isolated yield, again as a single diastereomer. No other diastereomer was detected in the crude reaction mixture. The (trimethylsilyl)methyl substituent and the C–C bond newly formed between the arene and 3 were assigned as trans to each other by a series of NMR analyses (1H, 13C, DEPT, COSY, HMQC, HMBC and NOESY).

Scheme 7. Synthesis of cyclophane (±)-4b from 1b

![Scheme 7](image)

The explanation for the diastereoselectivity observed in the photocyclization step is shown in Scheme 8. Although the 1,4-biradical species Ab generated from 1b potentially gives rise to four stereoisomers (E,Z)-Bb, (E,E)-Bb, (Z,Z)-Bb and (Z,E)-Bb, the formation of (Z,Z)-Bb and (Z,E)-Bb is disfavored because of steric repulsion arising between the trimethylsilylmethyl group and the ansa chain. As with the cases of (Z)- and (E)-Ba in scheme 3a, the quinodimethane (E,Z)-Bb having the outward-oriented hydroxy group undergoes thermal conrotatory electrocyclic ring closure to form trans-benzocyclobutenol (±)-5b diastereoselectively, whereas the isomer (E,E)-Bb bearing an inward-oriented hydroxy group reverts to the starting ketone 1b via facile 1,5-hydrogen shift.
The second ring-opening step occurs with central-to-planar chirality transfer\textsuperscript{13} (Scheme 9). The benzene ring of the deprotonated intermediate C\textsubscript{b} coordinates to rhodium to facilitate site-selective migration of the ipso sp\textsuperscript{2} carbon onto rhodium. For the ipso carbon to migrate onto rhodium, the benzene ring flips up toward rhodium. Accordingly, the developing C–Rh linkage is trans to the (trimethylsilyl)methyl substituent with respect to the newly expanded ansa chain. The rhodium with the COD ligand on it is sterically bulky enough to prohibit the ring flipping across the ansa chain. The intermediate D\textsubscript{b} then undergoes conjugate addition to 3 with retention of the upward orientation of the C–Rh linkage, producing (±)-4\textsubscript{b} stereoselectively.
**Scheme 9.** Reaction pathway from (±)-5b to 4b

Stereoselective production of (±)-4b from (±)-5b provides a strong support for the validity of the stereospecificity of β-carbon elimination. Nonetheless, there remains a possibility that the formation of the diastereomer (±)-4b is favored over that of the other diastereomer simply due to thermodynamic or kinetic reasons, rather than a mechanistic consequence. In order to examine this possibility, the author next carried out the rhodium-catalyzed reactions of diastereomeric benzo[cyclobutenols], trans- and cis-(±)-5c, which were prepared from 1c having an additional methyl group next to the trimethylsilyl-ethyl substituent (Scheme 10).

**Scheme 10.** Synthesis of metacyclophane (±)-4c from 1c

The result of the first photocyclization step of 1c contrasted with that of 1b, affording a diastereomer mixture of trans-(±)-5c and cis-(±)-5c (84%, 37:63). While there are four stereoisomers possibly generated from the biradical intermediate (Scheme 11), those
having an inward-oriented hydroxy group immediately revert to the starting \(1c\), as with the case of \(1b\). Unlike with \(1b\), however, the stereoisomer \((Z,Z)-Bc\) is more favored than \((E,Z)-Bc\) due to the steric repulsion arising between the (trimethylsilyl)methyl group and the added methyl group. Accordingly, conrotatory ring closure occurs with both \((E,Z)-Bc\) and \((Z,Z)-Bc\) to give a mixture of \(trans-(\pm)-5c\) and \(cis-(\pm)-5c\), respectively.

**Scheme 11. Structures of possible quinodimethane intermediates B**

Then, the two diastereomers \(trans-(\pm)-5c\) and \(cis-(\pm)-5c\) were separated by chromatography on silica gel, and each isolated diastereomer was subjected to the second ring-opening reaction. The diastereomer \(trans-(\pm)-5c\) with its hydroxy group directing upward (that is, trans to the (trimethylsilyl)methyl substituent) selectively furnished \(anti-(\pm)-4c\) with the newly formed C–C bond directing upward (that is, trans to the (trimethylsilyl)methyl substituent). On the other hand, the other diastereomer \(cis-(\pm)-5c\) with its hydroxy group directing downward (that is, cis to the (trimethylsilyl)methyl substituent) selectively furnished \(syn-(\pm)-4c\) with the newly formed C–C bond directing downward (that is, cis to the (trimethylsilyl)methyl substituent). Thus, a clear stereospecific relationship was observed with the pair of diastereomers \(trans-(\pm)-5c\) and \(cis-(\pm)-5c\) to establish that \(\beta\)-aryl elimination occurs in a stereospecific fashion.

Various orthocyclophanes \(1\) were successfully expanded into metacyclophanes \((\pm)-4\) via \((\pm)-5\) in a stereospecific manner by sequential action of light and rhodium (Table 1). The carbocyclic ketone \(1g\) was also transformed to \((\pm)-4g\) diastereoselectively, although the photocyclization suffered from the formation of the isomeric benzocyclobutenol \((\pm)-6\) (entry 5). The ring expansion of 11-membered cyclic ketone \(1h\) produced \((\pm)-4h\), which also possessed planar chirality stable at room temperature (entry 6).

Conclusions

The author has described a ring-expanding pathway from orthocyclophanes 1 to their constitutional isomers, metacyclophanes 2 by means of the sequential action of light and rhodium. Formally, the non-strained C–H and C–C bonds are cleaved and exchanged to form a product that is energetically uphill. The energy uptake during photocyclization step drives the transformation forward. Furthermore, the present reaction is successfully extended to the synthesis of metacyclophanes possessing planar chirality to demonstrate that stereospecific chirality transfer takes place during the process of rhodium-catalyzed C–C bond cleavage.
Experimental section

General. All reactions were carried out under an argon atmosphere unless otherwise noted. Photoreactions were carried out using RPR-100 photoreactor (Rayonet). Gel permeation chromatography (GPC) was carried out with a Japan Analytical Industry LC-9204. Flash column chromatography was performed with silica gel 60 N (Kanto). Preparative thin-layer chromatography was performed on silica gel plates with PF254 indicator (Merck). Infrared spectra were recorded on a Shimadzu FTIR DR-8000 spectrometer. \(^1\)H and \(^{13}\)C NMR spectra were recorded on a Varian Mercury vx400 (\(^1\)H at 400 MHz and \(^{13}\)C at 100 MHz) spectrometer using CDCl\(_3\) (\(^1\)H, \(\delta = 7.26\)) and CDCl\(_3\) (\(^{13}\)C, \(\delta = 77.0\)) as an internal standard unless otherwise noted. High-resolution mass spectra were recorded on a Thermofisher EXACTIVE (APCI). Optical rotation was measured by a JASCO P-1020 polarimeter with a sodium lamp. HPLC analysis was performed by 4.6 x 250 mm column.

Materials. Anhydrous THF, DCM, and Et\(_2\)O were purchased from Kanto Chemical Co. Anhydrous MeOH and DMF were purchased from Wako Pure Chemical Industries. Toluene and 1,4-dioxane were distilled from sodium/benzophenone ketyl. Methyl vinyl ketone was distilled from K\(_2\)CO\(_3\) and CaCl\(_2\) prior to use. B\(_1\),\(^{14}\) C\(_1\),\(^{14}\) G\(_1\),\(^{15}\) H\(_1\),\(^{16}\) [Rh(OH)(cod)]\(_2\),\(^{17}\) and Ru(H\(_2\))(CO)(PPh\(_3\))\(_3\)\(^{18}\) were prepared according to the literature procedures. All other commercially available chemical resources were used as received without further purification.

Photocyclization of orthocyclophane 1a

![Diagram of photocyclization of orthocyclophane 1a]

An anhydrous THF solution (5.0 ml) of 1a (21.8 mg, 0.10 mmol) in a Pyrex tube was irradiated under UV light (270–350 nm). After 15 h, the mixture was evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 5/1) to afford (±)-5a (20.0 mg, 0.092 mmol, 92%); IR (neat): 3385, 2920, 1603, 1546, 1456, 1047, 775 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 1.12–1.28\) (m, 1H), 1.35–1.64 (m, 5H), 1.69–1.80 (m, 1H), 1.83–1.97 (m, 1H), 2.06–2.19 (m, 1H), 2.28 (ddd, \(J = 14.4, 8.0, 1.6\) Hz, 1H), 3.13–3.24 (m, 2H), 3.91 (ddd, \(J = 10.4, 8.0, 2.0\) Hz, 1H), 4.57...
Chapter 4

Found m/z 219.1376.

**Rhodium-catalyzed ring opening of (±)-5a**

A mixture containing \([\text{Rh(OH)(cod)}]_{2}\) (1.1 mg, 2.5 mmol, 2.5 mol %) and benzocyclobutenol (±)-5a (21.4 mg, 0.10 mmol) in MeOH (0.50 ml) was stirred at 60 °C for 5 h. The reaction mixture was passed through a pad of Florisil\(^{\circledR}\), eluted with ethyl acetate and evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford metacyclophane 2a (15.7 mg, 0.072 mmol, 72%); IR (neat): 2922, 1697, 1587, 1161, 783 cm\(^{-1}\); \(^{1}H\) NMR: \( \delta = 0.98–1.11 \) (m, 2H), 1.33–1.47 (m, 2H), 1.61–1.79 (m, 4H), 2.26 (dd, \( J = 6.0, 6.0 \) Hz, 2H), 3.67 (s, 2H), 4.25 (dd, \( J = 4.8, 4.8 \) Hz, 2H), 6.66 (s, 1H), 6.76 (d, \( J = 7.2 \) Hz, 1H), 6.78–6.84 (m, 1H), 7.23 (dd, \( J = 8.0, 8.0 \) Hz, 1H); \(^{13}\)C NMR: \( \delta = 22.4, 22.7, 24.4, 31.3, 35.8, 50.9, 63.4, 112.1, 116.3, 121.7, 130.4, 135.9, 159.9, 209.8; \) HRMS (APCI): Calcd for \( \text{C}_{14}\text{H}_{19}\text{O}_{2} \), [M+H]\(^{+}\) 219.1380. Found m/z 219.1377.

**Synthesis of metacyclophane (±)-4a**

A mixture containing \([\text{Rh(OH)(cod)}]_{2}\) (1.2 mg, 2.5 mmol, 2.5 mol %), methyl vinyl ketone 3 (81.6 ml, 1.0 mmol) and (±)-5a (21.8 mg, 0.10 mmol) in toluene (0.50 ml) was stirred at room temperature for 10 h. The reaction mixture was passed through a pad of Florisil\(^{\circledR}\) using ethyl acetate as the eluent, and then the filtrate was evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 5/1) to afford (±)-4a (19.9 mg, 0.069 mmol, 69%); IR (neat):
2941, 1705, 1454, 1232, 910, 729 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 0.25–0.45\) (m, 1H), 0.51–0.68 (m, 1H), 0.77–0.98 (m, 3H), 1.27–1.61 (m, 3H), 1.93–2.13 (m, 5H), 2.50 (ddd, \(J = 17.6, 9.2, 6.4\) Hz, 1H), 2.61 (ddd, \(J = 17.6, 9.2, 5.6\) Hz, 1H), 2.88 (ddd, \(J = 13.6, 8.8, 6.4\) Hz, 1H), 3.30 (ddd, \(J = 14.4, 9.6, 5.6\) Hz, 1H), 3.44 (d, \(J = 14.6\) Hz, 1H), 3.95 (d, \(J = 14.6\) Hz, 1H), 4.08 (ddd, \(J = 12.0, 6.4, 2.4\) Hz, 1H), 4.21 (ddd, \(J = 11.2, 8.8, 2.0\) Hz, 1H), 6.87 (d, \(J = 7.6\) Hz, 1H), 6.94 (d, \(J = 7.6\) Hz, 1H), 7.14 (dd, \(J = 8.0, 7.6\) Hz, 1H); \(^{13}\)C NMR: \(\delta = 21.8, 22.0, 22.6, 26.4, 28.6, 29.7, 36.7, 44.6, 50.9, 72.1, 120.3, 125.9, 127.8, 134.2, 134.3, 157.6, 207.6, 209.3\); HRMS (APCI): Calcd for \(C_{18}H_{25}O_3\), [M+H]\(^+\) 289.1798. ### Synthesis of (+)-4a

![Chemical Structure](image)

The racemic mixture of (±)-5a was separated by chiral preparative HPLC (Daicel CHIRALPAK OZ-H column, hexane:i-PrOH = 90:10). [\(\alpha\)]\(^{25}\)\(_D\) = +74.0 (c = 1.1 x 10\(^{-2}\) M in CHCl\(_3\)). A mixture containing [Rh(OH)(cod)]\(_2\) (1.7 mg, 3.8 mmol, 2.5 mol %), methyl vinyl ketone 3 (122.4 mmol, 1.5 mmol), and (+)-5a (33.7 mg, 0.15 mmol, >99:1 er) in toluene (0.90 ml) was stirred at room temperature for 10 h. The reaction mixture was passed through a pad of Florisil\(^\circledR\) using ethyl acetate as the eluent, and then the filtrate was evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 5/1) to afford metacyclophane (+)-4a (32.0 mg, 0.11 mmol, 72%, >99:1 er) (Daicel CHIRALPAK IB column, hexane/i-PrOH = 90/10, 0.40 ml min\(^{-1}\), retention times: \(t_1 = 9.322\) min, \(t_2 = 11.09\) min), [\(\alpha\)]\(^{25}\)\(_D\) = +68.4 (c = 2.1 x 10\(^{-2}\) M in CHCl\(_3\)).

**Synthesis of 1a**

A solution of 4-pentenylmagnesium bromide in Et\(_2\)O (1.0 M, 35.0 mL, 35.0 mmol) and triethylamine (5.0 mL, 37.0 mmol) in anhydrous toluene (20 mL) was cooled to 0 °C. 6-Methyalsalicylate A\(_1\) (1.80 g, 10.0 mmol) in anhydrous toluene (4 mL) was added dropwise and the reaction mixture was stirred at room temperature for 12 h. A saturated solution of ammonium chloride (10 mL) was added and the mixture was extracted with ethyl acetate, washed with water and brine, dried over MgSO\(_4\), and evaporated. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford ketone A\(_2\) (1.96 g, 9.6 mmol, 96%); IR (neat): 3337, 2934, 1680, 1464, 1285, 912, 779 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 1.85\) (tt, \(J = 7.2, 7.2\) Hz, 2H), 2.09–2.18 (m, 2H), 2.56 (s, 3H), 2.94 (t, \(J = 7.6\) Hz, 2H), 4.95–5.07 (m, 2H), 5.80 (ddt,
$J = 16.8, 10.4, 6.4 \text{ Hz, 1H}, 6.68–6.74 (m, 1H), 6.82 (dd, J = 8.0, 0.8 \text{ Hz, 1H}), 7.25 (dd, J = 8.0, 7.6 \text{ Hz, 1H}), 11.62 (s, 1H)$; $^{13}$C NMR: $\delta = 23.8, 24.1, 33.1, 43.6, 115.4, 116.2, 122.5, 123.1, 134.0, 137.8, 138.6, 161.5, 208.8$; HRMS (APCI): Calcd for C$_{13}$H$_{17}$O$_2$, [M+H]$^+$ 205.1223. Found m/z 205.1219.

To a stirred solution of A$_2$ (1.96 g, 9.6 mmol) in DMF (30 mL) were added K$_2$CO$_3$ (1.94 g, 14.0 mmol) and allyl bromide (1.80 g, 15.0 mmol). After stirring the reaction mixture for 2 h at 80 °C, water was added and extracted with ethyl acetate, washed with water and brine, dried over MgSO$_4$, and evaporated. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford A$_3$ (2.35 g, 9.5 mmol, 99%); IR (neat): 2928, 1695, 1466, 1259, 991, 912, 775 cm$^{-1}$; $^1$H NMR: $\delta =$ 1.80 (tt, $J = 7.2, 7.2$ Hz, 2H), 2.07–2.17 (m, 2H), 2.21 (s, 3H), 2.80 (t, $J = 7.6$ Hz, 2H), 4.53 (ddd, $J = 5.2, 1.2, 1.2$ Hz, 2H), 4.98 (ddt, $J = 10.4, 2.4, 1.2$ Hz, 1H), 5.02 (ddt, $J = 17.2, 1.6, 1.6$ Hz, 1H), 5.25 (ddt, $J = 10.4, 1.2, 1.2$ Hz, 1H), 5.35 (ddt, $J = 17.2, 1.6, 1.6$ Hz, 1H), 5.80 (ddt, $J = 16.8, 10.0, 6.4$ Hz, 1H), 5.99 (ddt, $J = 17.2, 10.4, 5.2$ Hz, 1H), 6.73 (d, $J = 8.4$ Hz, 1H), 6.79 (d, $J = 7.6$ Hz, 1H), 7.18 (dd, $J = 8.0, 8.0$ Hz, 1H); $^{13}$C NMR: $\delta =$ 18.9, 22.7, 33.1, 43.8, 69.1, 109.5, 115.0, 117.5, 123.0, 129.5, 131.6, 132.8, 135.4, 138.2, 155.0, 207.9; HRMS (APCI): Calcd for C$_{16}$H$_{21}$O$_2$, [M+H]$^+$ 245.1536. Found m/z 245.1531.

To a solution of Grubbs 1st generation catalyst (24.6 mg, 0.030 mmol) in anhydrous CH$_2$Cl$_2$ (200 mL) were added A$_3$ (733 mg, 3.0 mmol) at 55 °C. After stirring for 6 h, the reaction mixture was concentrated. The residue was purified by column chromatography on silica gel (ethyl acetate) to afford crude A$_4$, which was subjected to the next hydrogenation reaction without further purification.

A mixture of A$_4$ and Pd/C (10 wt. %, 150 mg) in anhydrous THF (15 mL) was stirred under hydrogen atmosphere (1 atm) at room temperature for 3 h. The reaction mixture was filtered through a celite pad and concentrated. The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford 1a (242 mg, 1.11 mmol, 37%); IR (neat): 2928, 1693, 1460, 1259, 1072, 777 cm$^{-1}$; $^1$H NMR: $\delta =$ 1.51–1.69 (m, 4H), 1.72–1.82 (m, 4H), 2.23 (s, 3H), 2.57–2.63 (m, 2H), 4.15 (t, $J = 5.2$ Hz, 2H), 6.77 (d, $J = 8.4$ Hz, 1H), 6.81 (d, $J = 7.6$ Hz, 1H), 7.20 (dd, $J = 8.0, 8.0$ Hz, 1H); $^{13}$C NMR: $\delta =$ 18.7, 24.0, 25.4, 26.6, 27.6, 43.1, 71.4, 111.0, 123.4, 129.7, 132.5, 135.1, 156.4, 209.4; HRMS (APCI): Calcd for C$_{14}$H$_{19}$O$_2$, [M+H]$^+$ 219.1380. Found m/z 219.1375.
Synthesis of 1b

To a stirred solution of 2-(allyloxy)benzaldehyde B1 (1.62 g, 10.0 mmol) in anhydrous THF (30 mL) at 0 °C was added 4-pentenylmagnesium bromide in anhydrous Et₂O (1.0 M, 12.0 mL, 12.0 mmol) slowly. After stirring for 2 h at room temperature, saturated NH₄Cl aq was added at 0 °C. The mixture was extracted with Et₂O, washed with water and brine, dried over Na₂SO₄, and evaporated to afford crude B2. This compound was used without further purification.

To a solution of oxalyl chloride (1.0 mL, 11.7 mmol) in anhydrous CH₂Cl₂ was added dropwise DMSO (1.1 mL, 15.5 mmol) at –78 °C. After stirring for 20 min., a solution of crude B2 in anhydrous CH₂Cl₂ (10 mL) was added slowly to the mixture. The reaction mixture was stirred for 1 h at –78 °C, Et₃N (7.5 mL) was added by syringe. After stirring at room temperature for 40 min., water was added. The mixture was extracted with CH₂Cl₂, washed with water and brine, dried over MgSO₄, and evaporated. The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford B3 (1.64 g, 7.13 mmol, 71%); IR (neat): 2934, 1670, 1595, 1448, 1234, 991, 752 cm⁻¹; ¹H NMR: δ = 1.79 (tt, J = 7.2, 7.2 Hz, 2H), 2.07–2.15 (m, 2H), 3.01 (t, J = 7.2 Hz, 2H), 4.62 (dt, J = 5.2, 1.6 Hz, 2H), 4.93–4.98 (m, 1H), 5.02 (ddt, J = 17.2, 1.6, 1.2 Hz, 1H), 5.29–5.35 (m, 1H), 5.42 (ddt, J = 17.2, 1.6, 1.2 Hz, 1H), 5.80 (ddt, J = 16.8, 10.4, 6.4 Hz, 1H), 6.01–6.13 (m, 1H), 6.93 (d, J = 8.4 Hz, 1H), 6.97–7.03 (m, 1H), 7.38–7.45 (m, 1H), 7.65 (dd, J = 8.0, 2.0 Hz, 1H); ¹³C NMR: δ = 23.5, 33.3, 43.1, 69.3, 112.6, 114.9, 118.1, 120.8, 128.9, 130.1, 132.6, 133.0, 138.3, 157.3, 202.8; HRMS (APCI): Calcd for C₁₅H₁₉O₂, [M+H]⁺ 231.1380. Found m/z 231.1377.

To a solution of Grubbs 1st generation catalyst in anhydrous CH₂Cl₂ (100 mL) was added B3 (230 mg, 1.0 mmol) at 50 °C. After stirring for 5 h, the reaction mixture was concentrated. The residue was purified by flash column chromatography on silica gel (ethyl acetate) to afford crude B4, which was subjected to the next hydrogenation
reaction without further purification.

A mixture of B4 and Pd/C (10 wt.%, 53.0 mg) in anhydrous THF (10 mL) was stirred under hydrogen atmosphere (1 atm) at room temperature for 3 h. The reaction mixture was filtered through a celite pad and concentrated. The residue was purified by flash column chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford B5 (75 mg, 0.37 mmol, 37%); IR (neat): 2926, 1668, 1559, 1450, 1292, 1003, 752 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 1.53–1.64\) (m, 2H), 1.69–1.90 (m, 6H), 2.78 (t, \(J = 7.2\) Hz, 2H), 4.15 (t, \(J = 6.4\) Hz, 2H), 6.95 (d, \(J = 8.4\) Hz, 1H), 6.98–7.04 (m, 1H), 6.7 (dd, \(J = 7.6, 1.6\) Hz, 1H), \(^{13}\)C NMR: \(\delta = 23.0, 23.6, 27.4, 27.5, 41.3, 70.1, 114.0, 121.1, 129.71, 129.74, 133.2, 158.3, 203.9\); HRMS (APCI): Calcd for C\(_{13}\)H\(_{17}\)O\(_2\), [M+H]\(^+\) 205.1223. Found m/z 205.1218.

A mixture containing RuH\(_2\)(CO)(PPh\(_3\))\(_3\) (9.2 mg, 1.0 mmol, 10 mol %), vinyltrimethylsilane (100 mg, 1.0 mmol), and B5 (20.4 mg, 0.10 mmol) in toluene (0.10 mL) was stirred at 135 °C for 15 h. After being cooled to room temperature, the reaction mixture was passed through a pad of Florisil\(^\circledR\) and eluted with ethyl acetate, and evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford 1b (25.5 mg, 0.084 mmol, 84%); IR (neat): 2930, 1695, 1456, 1246, 831 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 0.00\) (s, 9H), 0.74–0.85 (m, 2H), 1.51–1.69 (m, 4H), 1.72–1.84 (m, 4H), 2.44–2.53 (m, 2H), 2.58–2.65 (m, 2H), 4.14 (t, \(J = 5.2\) Hz, 2H), 6.75 (d, \(J = 8.4\) Hz, 1H), 6.86 (d, \(J = 7.6\) Hz, 1H), 7.23 (dd, \(J = 8.0, 8.0\) Hz, 1H); \(^{13}\)C NMR: \(\delta = -1.9, 19.4, 24.1, 25.3, 26.5, 26.9, 27.7, 43.3, 71.5, 110.7, 121.7, 129.9, 131.8, 143.0, 156.4, 209.2\); HRMS (APCI): Calcd for C\(_{18}\)H\(_{29}\)O\(_2\)Si, [M+H]\(^+\) 305.1931. Found m/z 305.1923.

**Synthesis of 1c**

![Synthesis Diagram]

1c was synthesized from C3 in the same way as 1b from B1.

C3: IR (neat): 2926, 1670, 1495, 1236, 991, 910, 806 cm\(^{-1}\); \(^1\)H NMR: \(\delta = 1.78\) (tt, \(J = 198\).
Chapter 4

Synthesis of 1d

A mixture containing Cp*RhCl$_2$ (3.7 mg, 6.0 mmol, 2.0 mol %), styrene (46.8 mg, 0.45 mmol), B5 (61.6 mg, 0.30 mmol), AgSbF$_6$ (8.3 mg, 24 mmol, 8.0 mol %), and Cu(OAc)$_2$ (108 mg, 0.60 mmol) in 1,4-dioxane (1.5 mL) was stirred at 120 °C for 13 h. After being cooled to room temperature, the reaction mixture was passed through a pad of Florisil$^\text{®}$ and eluted with ethyl acetate, and evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) and gel permeation chromatography to afford D1 (62.8 mg, 0.204 mmol, 68%); IR (neat): 2928, 1693, 1568, 1462, 1252, 691 cm$^{-1}$; $^1$H NMR: $\delta = 1.50–1.62$ (m, 2H), 1.63–1.85 (m, 6H), 2.60–2.70 (m, 2H), 4.18 (t, $J = 5.2$ Hz, 2H), 6.82–6.89 (m, 1H), 7.06 (d, $J = 5.2$ Hz, 2H), 7.29–7.35 (m, 2H), 7.45 (d, $J = 8.4$ Hz, 1H), 7.72 (t, $J = 8.4$ Hz, 1H), 7.85 (t, $J = 1.6$ Hz, 1H); $^{13}$C NMR: $\delta = 20.3$, 23.1, 23.5, 27.1, 27.4, 41.2, 70.3, 114.3, 129.3, 129.7, 130.5, 133.7, 156.2, 204.0; HRMS (APCI): Calcd for $\text{C}_{16}\text{H}_{21}\text{O}_{2}$, [M+H]$^+$ 245.1536. Found m/z 245.1533.
16.0 Hz, 1H), 7.10 (d, J = 16.0 Hz, 1H), 7.24–7.38 (m, 5H), 7.45–7.50 (m, 2H); $^{13}$C NMR: $\delta = 23.8, 25.4, 26.4, 27.3, 43.8, 71.4, 112.4, 118.3, 124.5, 126.7, 127.9, 128.5, 129.9, 131.6, 131.7, 134.6, 136.8, 156.3, 209.1; HRMS (APCI): Calcd for C$_{21}$H$_{23}$O$_2$, [M+H]$^+$ 307.1693. Found m/z 307.1682.

A mixture of D1 (62.8 mg, 0.204 mmol) and Pd/C (10 wt. %, 12.4 mg) in anhydrous THF (5 mL) was stirred under hydrogen atmosphere (1 atm) at room temperature for 2 h. The reaction mixture was filtered through a celite pad and concentrated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford 1d (60.2 mg, 0.196 mmol, 96%); IR (neat): 2359, 1690, 1456, 1267, 1072, 694 cm$^{-1}$; $^1$H NMR: $\delta = 1.51–1.70$ (m, 4H), 1.71–1.87 (m, 4H), 2.48–2.55 (m, 2H), 2.76–2.84 (m, 2H), 2.85–2.92 (m, 2H), 4.15 (t, J = 5.2 Hz, 2H), 6.80 (d, J = 7.6 Hz, 1H), 6.84 (d, J = 7.6 Hz, 1H), 7.11–7.30 (m, 6H); $^{13}$C NMR: $\delta = 24.2, 25.2, 26.5, 27.8, 35.0, 38.2, 43.0, 71.5, 111.2, 122.6, 125.9, 128.3, 128.5, 129.9, 132.4, 139.2, 141.6, 156.6, 209.2; HRMS (APCI): Calcd for C$_{21}$H$_{25}$O$_2$, [M+H]$^+$ 309.1849. Found m/z 309.1841.

**Synthesis of 1e**

![Synthesis diagram]

**E2** was synthesized from **B5** in the same way as **1d** from **B5**.

E1: IR (neat): 2937, 1715, 1456, 1269, 1171, 789 cm$^{-1}$; $^1$H NMR: $\delta = 1.51–1.84$ (m, 8H), 2.61–2.68 (m, 2H), 3.77 (s, 3H), 4.17 (t, J = 5.2 Hz, 2H), 6.37 (d, J = 16.0 Hz, 1H), 6.96 (d, J = 8.0 Hz, 1H), 7.23 (d, J = 8.0 Hz, 1H), 7.34 (dd, J = 8.0, 8.0 Hz, 1H), 7.59 (d, J = 16.0 Hz, 1H); $^{13}$C NMR: $\delta = 23.8, 25.3, 26.5, 27.5, 43.6, 51.8, 71.7, 114.9, 119.5, 120.9, 130.3, 132.0, 133.2, 140.9, 156.6, 166.7, 207.9; HRMS (APCI): Calcd for C$_{17}$H$_{21}$O$_4$ [M+H]$^+$ 289.1434, Found m/z 289.1427.

E2: IR (neat): 2928, 1734, 1693, 1454, 1261, 1169, 1072 cm$^{-1}$; $^1$H NMR: $\delta = 1.51–1.70$ (m, 4H), 1.73–1.86 (m, 4H), 2.57–2.67 (m, 4H), 2.77–2.86 (m, 2H), 3.65 (s, 3H), 4.14 (t,
To a lithium aluminum hydride (68.4 mg, 1.8 mmol) in anhydrous THF (2.0 mL) was added dropwise E2 (186 mg, 0.60 mmol) in anhydrous THF (1.0 mL) at 0 °C. After stirring the reaction mixture for 10 h at room temperature, ethyl acetate and water were added slowly at 0 °C. The mixture was extracted with ethyl acetate, washed with water and brine, dried over Na₂SO₄, and evaporated. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 3/1) to afford E3 (137 g, 0.52 mmol, 86%); IR (neat): 3296, 2930, 1452, 1252, 1030, 731 cm⁻¹; ¹H NMR: δ = 1.07–1.37 (m, 2H), 1.40–1.55 (m, 2H), 1.59–1.91 (m, 7H), 1.92–2.05 (m, 1H), 2.59–2.71 (m, 1H), 2.86–2.99 (m, 1H), 3.26–3.50 (m, 2H), 3.52–3.66 (m, 2H), 4.07–4.18 (m, 1H), 4.25–4.38 (m, 1H), 5.46 (dd, J = 8.0, 4.0 Hz, 1H), 6.74 (d, J = 8.0 Hz, 1H), 6.80 (d, J = 7.6 Hz, 1H), 7.13 (dd, J = 8.0, 7.6 Hz, 1H); ¹³C NMR (CD₃CN): δ = 23.6, 27.2, 27.3, 28.1, 29.7, 31.5, 35.6, 62.2, 68.2, 71.9, 112.2, 124.6, 128.4, 132.8, 143.1, 158.0; HRMS (APCI): Calcd for C₁₇H₂₃O₄, [M+H]⁺ 291.1591. Found m/z 291.1583.

To a sodium hydride (60 % in oil dispersion, 28.4 mg, 1.8 mmol) in anhydrous DMF (1.0 mL) was added dropwise E3 (137 mg, 0.52 mmol) in anhydrous DMF (1.0 mL) at 0 °C. After stirring for 20 min., BnBr (120 mg, 0.70 mmol) was added to the reaction mixture. The reaction mixture was stirred for 3 h at room temperature, then water was added. The mixture was extracted with ethyl acetate, washed with water and brine, dried over Na₂SO₄, and evaporated. The residue was purified by column chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford E4 (70 mg, 0.20 mmol, 38%); IR (neat): 3422, 2926, 1578, 1452, 1234, 1028, 733 cm⁻¹; ¹H NMR: δ = 1.18–2.13 (m, 12H), 2.68–2.87 (m, 2H), 3.53 (t, J = 6.0 Hz, 2H), 3.89 (br s, 1H), 4.05–4.15 (m, 1H), 4.36–4.45 (m, 1H), 4.51 (d, J = 12.0 Hz, 1H), 4.54 (d, J = 12.0 Hz, 1H), 5.37 (dd, J = 6.4, 3.6 Hz, 1H), 6.77 (d, J = 8.0 Hz, 1H), 6.81 (d, J = 6.8 Hz, 1H), 7.11–7.17 (m, 1H), 7.25–7.40 (m, 5H); ¹³C NMR: δ = 22.8, 27.2, 27.35, 27.44, 29.3, 31.5, 35.6, 69.6, 70.1, 71.5, 72.8, 111.5, 123.4, 127.5, 127.56, 127.62, 128.3, 130.7, 138.5, 140.7, 157.6; HRMS (APCI): Calcd for C₂₃H₃₀O₃Na, [M+Na]⁺ 377.2087. Found m/z 377.2079.

To a solution of oxalyl chloride (30.4 mg, 0.24 mmol) in anhydrous CH₂Cl₂ (1.0 mL) was added dropwise DMSO (21.5 mL, 0.30 mmol) at –78 °C. After stirring for 20 min., a solution of crude E2 (70.0 mg, 0.20 mmol) in anhydrous CH₂Cl₂ (1.0 mL) was added slowly to the mixture. The reaction mixture was stirred for 1 h at –78 °C, Et₃N (1.0 mL)
was added by syringe. After stirring at room temperature for 40 min., water was added. The mixture was extracted with CH₂Cl₂, washed with water and brine, dried over MgSO₄, and evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 10/1) to afford 1e (17.4 g, 0.174 mmol, 87%); IR (neat): 2928, 1693, 1454, 1261, 1090, 733 cm⁻¹; ¹H NMR: δ = 1.50–1.70 (m, 4H), 1.73–1.83 (m, 4H), 1.84–1.95 (m, 2H), 2.54–2.67 (m, 4H), 3.48 (t, J = 6.0 Hz, 2H), 4.14 (t, J = 5.2 Hz, 2H), 6.78 (d, J = 8.4 Hz, 1H), 6.84 (d, J = 7.6 Hz, 1H), 7.19–7.37 (m, 6H); ¹³C NMR: δ = 24.1, 25.3, 26.5, 27.8, 31.5, 43.2, 69.5, 71.5, 72.8, 111.1, 122.5, 127.5, 127.7, 128.3, 129.8, 132.5, 138.5, 139.4, 156.4, 209.3; HRMS (APCI): Calcd for C₂₃H₂₉O₃, [M+H]⁺ 353.2111. Found m/z 353.2104.

Synthesis of 1f

![Chemical structure](image)

1f was synthesized from B5 in the same way as 1b from B5. Allyltrimethylsilane was employed instead of vinyl trimethylsilane. 24% yield; IR (neat): 2928, 1695, 1246, 833 cm⁻¹; ¹H NMR: δ = −0.04 (s, 9H), 0.45–0.55 (m, 2H), 1.48–1.70 (m, 6H), 1.71–1.86 (m, 4H), 2.51 (t, J = 7.6 Hz, 2H), 2.56–2.65 (m, 2H), 4.14 (t, J = 5.2 Hz, 2H), 6.77 (d, J = 8.0 Hz, 1H), 6.83 (d, J = 8.0 Hz, 1H), 7.23 (dd, J = 8.0, 7.6 Hz, 1H); ¹³C NMR: δ = −1.7, 16.8, 24.2, 25.3, 26.4, 26.5, 27.8, 36.6, 43.3, 71.5, 110.9, 122.5, 129.7, 132.4, 140.2, 156.4, 209.3; HRMS (APCI): Calcd for C₁₉H₃₁O₂Si, [M+H]⁺ 319.2088. Found m/z 319.2080.

Synthesis of 1g

![Chemical structure](image)

G5 was synthesized from G1 in the same way with B5 from B1. The spectroscopic
data of G5 was identical to the reported values.19

**G3**: IR (neat): 2934, 1684, 993, 752 cm⁻¹; ¹H NMR: δ = 1.82 (tt, J = 7.2, 7.2 Hz, 2H), 2.10–2.19 (m, 2H), 2.29–2.38 (m, 2H), 2.85–2.92 (m, 4H), 4.92–5.07 (m, 4H), 5.73–5.92 (m, 2H), 7.23–7.28 (m, 2H), 7.38 (ddd, J = 8.0, 8.0, 1.6 Hz, 1H), 7.56 (dd, J = 8.0, 1.6 Hz, 1H); ¹³C NMR: δ = 23.3, 33.1, 33.3, 35.8, 41.2, 114.9, 115.3, 125.8, 128.1, 130.9, 131.1, 138.0, 138.6, 141.3, 204.8; HRMS (APCI): Calcd for C₁₆H₂₁O, [M+H⁺]⁺ 229.1587. Found m/z 229.1582.

A mixture containing RuH₂(CO)(PPh₃)₃ (36.6 mg, 0.040 mmol, 10 mol %), vinyltrimethylsilane (400 mg, 4.0 mmol), and G5 (80.8 mg, 0.40 mmol) in mesitylene (0.60 mL) was stirred at 180 °C for 11 h. After being cooled to room temperature, the reaction mixture was passed through a pad of Florisil®, eluted with ethyl acetate and evaporated. The residue was purified by preparative thin-layer chromatography on silica gel (hexane/ethyl acetate = 20/1) to afford 1g (105.7 mg, 0.35 mmol, 88%); IR (neat): 2930, 1684, 1246, 829 cm⁻¹; ¹H NMR (C₆D₆): δ = –0.08 (s, 9H), 0.70–0.81 (m, 2H), 0.96–1.10 (m, 2H), 1.15–1.31 (m, 4H), 1.40–1.52 (m, 2H), 1.62–1.84 (m, 2H), 2.44–2.56 (m, 2H), 2.59–2.97 (m, 4H), 6.89–6.94 (m, 2H), 7.09 (dd, J = 7.6, 7.6 Hz, 1H); ¹³C NMR: δ = –1.9, 18.9, 22.5, 22.6, 23.5, 27.9, 28.5, 28.6, 29.6, 45.4, 126.2, 127.7, 129.0, 138.8, 139.5, 142.0, 212.2; HRMS (APCI): Calcd for C₁₉H₃₁OSi, [M+H⁺]⁺ 303.2139. Found m/z 303.2132.

**Synthesis of 1h**

1h was synthesized from H1 in the same way as 1b from B1.

**H3**: IR (neat): 2924, 1668, 1595, 1448, 1238, 901, 750 cm⁻¹; ¹H NMR: δ = 1.78 (tt, J = 7.2, 7.2 Hz, 2H), 2.07–2.15 (m, 2H), 2.60 (ddt, J = 6.8, 6.4, 1.2, 1.2 Hz, 2H), 3.01 (t, J = 7.6 Hz, 2H), 4.11 (t, J = 6.4 Hz, 2H), 4.96 (ddt, J = 10.4, 2.4, 1.2 Hz, 1H), 5.02 (ddt, J = 16.8, 1.6, 1.6 Hz, 1H), 5.13 (ddt, J = 10.4, 1.6, 1.6 Hz, 1H), 5.19 (ddt, J = 17.2, 1.6, 1.6 Hz, 1H), 5.81 (ddt, J = 16.8, 10.0, 6.4 Hz, 1H), 5.90 (ddt, J = 16.8, 10.4, 6.8 Hz, 1H),
6.93 (d, \( J = 8.4 \) Hz, 1H), 6.98 (ddd, \( J = 7.2, 7.2, 0.8 \) Hz, 1H), 7.42 (ddd, \( J = 8.4, 7.2, 2.0 \) Hz, 1H), 7.66 (dd, \( J = 7.6, 2.0 \) Hz, 1H); \(^{13}\)C NMR: \( \delta = 23.5, 33.3, 33.6, 43.3, 67.6, 112.1, 114.8, 117.4, 120.6, 128.7, 130.2, 133.1, 134.3, 138.4, 157.7, 202.9 \); HRMS (APCI) Calcd for \( \text{C}_{16}\text{H}_{21}\text{O}_{2} \), \([\text{M+H}]^+\) 245.1536, found 245.1532.

**H5**: IR (neat): 2928, 1668, 1595, 1447, 1242, 1011, 750 cm\(^{-1}\); \(^1\)H NMR: \( \delta = 1.46–1.69 \) (m, 6H), 1.78–1.97 (m, 4H), 2.83 (t, \( J = 6.4 \) Hz, 2H), 4.13 (t, \( J = 5.2 \) Hz, 2H), 6.89 (d, \( J = 8.4 \) Hz, 1H), 6.93–6.99 (m, 1H), 7.35–7.42 (m, 1H), 7.44 (dd, \( J = 7.6, 2.0 \) Hz, 1H); \(^{13}\)C NMR: \( \delta = 24.3, 24.9, 25.1, 25.8, 26.4, 40.8, 69.6, 112.0, 120.4, 128.5, 131.2, 132.3, 157.3, 207.0 \); HRMS (APCI): Calcd for \( \text{C}_{14}\text{H}_{19}\text{O}_{2} \), \([\text{M+H}]^+\) 219.1380. Found m/z 219.1374.

**1h**: IR (neat): 2924, 1697, 1578, 1447, 1254, 831 cm\(^{-1}\); \(^1\)H NMR: \( \delta = 0.00 \) (s, 9H), 0.74–0.87 (m, 2H), 1.42–1.68 (m, 6H), 1.79–1.92 (m, 4H), 2.39–2.49 (m, 2H), 2.68–2.75 (m, 2H), 3.98 (t, \( J = 4.8 \) Hz, 2H), 6.63 (d, \( J = 8.4 \) Hz, 1H), 6.79 (d, \( J = 7.6 \) Hz, 1H), 7.20 (dd, \( J = 8.0, 8.0 \) Hz, 1H); \(^{13}\)C NMR: \( \delta = -1.9, 19.5, 22.7, 23.5, 24.4, 24.9, 26.3, 26.9, 41.5, 68.4, 107.6, 120.5, 129.6, 131.9, 142.2, 155.5, 209.8 \); HRMS (APCI): Calcd for \( \text{C}_{19}\text{H}_{31}\text{O}_{2}\text{Si} \), \([\text{M+H}]^+\) 319.2088. Found m/z 319.2080.

**Computational study**

All calculations were performed with Gaussian 09 software package\(^{20}\). The density functional theory (DFT) method with the B3LYP (Becke's three-parameter hybrid functional\(^{21}\), LYP correlation functional\(^{22}\)) functional was utilized to fully optimize all the stationary points on the potential energy surface (PES) without symmetry and geometric constraints, in conjunction with the 6-31G(d) basis set. Zero-point energy, enthalpy, and Gibbs free energy at 298.15 K and 1 atm were estimated from the gas-phase studies. Harmonic vibration frequency calculations at the same level were performed to verify all stationary points have no imaginary frequency.

Abstract

1-Alkoxybenzocyclobutenes undergo ring-opening hydrogenolysis by a palladium on carbon catalyst. The proximal C(sp$^2$)–C(sp$^3$) bond is site-selectively cleaved and hydrogenated in preference to the benzylic carbon–oxygen bond and the thermally labile the distal C(sp$^3$)–C(sp$^3$) bond.
Introduction

Hydrogenation is one of the fundamental reactions frequently utilized in organic synthesis. A palladium catalyst shows the high catalytic activity towards the reduction of various unsaturated functionalities such as alkenes, alkynes, arenes, carbonyl compounds, and nitrogen-containing multiple bonds. Moreover, hydrogenolysis of a benzylic carbon–oxygen bond can also be performed in the presence of a palladium catalyst to deliver the corresponding alcohol and toluene. In addition to these typical reactions of functional groups, hydrogenolysis of carbon–carbon (C–C) σ-bonds has also been reported. Not only small cycloalkanes but also unstrained α-benzyl meldrum’s acid undergo hydrogenolysis of the C–C σ-bond.

As shown in previous chapters, the author has found that a rhodium catalyst induced ring opening of benzocyclobutenols with site-selective cleavage of the proximal C(sp^2)–C(sp^3) bonds. In the course of these studies, the author found that a palladium on charcoal catalyst showed the catalytic activity to cleave the proximal C(sp^2)–C(sp^3) bond of alkoxybenzocyclobutenes under hydrogen atmosphere. The proximal C(sp^2)–C(sp^3) bond is selectively cleaved in preference to the seemingly more reactive benzylic C–O bond and the thermally labile C(sp^3)–C(sp^3) bond.

Scheme 1. Hydrogenolysis of 1-alkoxybenzocyclobutenes with site-selectivity

Results and Discussions

Initially, the author optimized the reaction conditions (Table 1). When 1-methoxybenzocyclobutene 1a was stirred in the presence of a catalytic amount of Pd/C under atmospheric hydrogen in methanol, ring-opening product 2a was obtained in 5% yield with the generation of benzyl butyl ketone 3a and a trace amount of 4a (entry 1). Similarly, the toluene solution of 1a didn’t proceed the reaction completely to recover the starting material 1a (entry 2). In contrast, when ethyl acetate was employed as a solvent, the starting material 1a was consumed to afford 2a in moderate yield (entry 3). Dichloromethane improved the selectivity to reduce the formation of 3a (entry 4). When molecular sieves 4A was added to the reaction system, the formation of
benzyl butyl ketone \(3a\) was suppressed to afford the target compound \(2a\) in 82% isolated yield with a trace amount of \(4a\) (entry 5). There was no product derived from hydrogenolysis of the benzylic C–O bond and the other C–C bonds including the thermally labile C(sp\(^3\))–C(sp\(^3\)) bond and the sterically less-hindered C(sp\(^2\))–C(sp\(^3\)) bond.

\(^a\) Reaction conditions: methoxybenzocyclobutene \(1a\) (0.20 mmol), metal catalyst (5 mol %) and solvent (3.0 mL) were stirred under hydrogen for 5 h at room temperature. \(^b\) NMR yield. \(^c\) Isolated yield.

To obtain the mechanistic insight, the author conducted following experiments. When methoxycyclobutane \(1b\) was subjected to the identical reaction conditions, the benzylic C–O bond was cleaved to afford the product \(5b\) in 21% yield with the recovery of starting material \(1b\) in 52% yield. However, C–C bond cleavage product \(2b\) was not detected, indicating that the fused benzene ring facilitates hydrogenolysis of C–C bond (Scheme 2a). Replacement of the methoxy group of \(1a\) with an acetoxy group completely suppress the hydrogenolysis of the C(sp\(^2\))–C(sp\(^3\)) bond and instead reduction of the benzene ring took place to give \(4c\) in 81% isolated yield (Scheme 2b). Moreover, hydrogenation of simple benzocyclobutene \(1d\) also failed to give ethylbenzene \(2d\) (Scheme 2c). The reduction of benzene ring took place to afford some saturated compound. These results suggest that an electron-donating nature of the oxygen atom accelerates the hydrogenolysis of the C(sp\(^2\))–C(sp\(^3\)) bond.
Scheme 2. Mechanistic studies

(a) Based on these experimental results, the author tentatively assumes 2a is produced from 1a through the mechanistic scenario as follows. Initially, dihydrogen is split into two hydrogen atoms on the surface of Pd/C. The benzene ring of the benzocyclobutene 1a is adsorbed on Pd/C, which induces cleavage of the proximal C(sp^2)–C(sp^3) bond with assistance of electron donation from the lone pair of electrons on oxygen. Hydride is transferred to the oxocarbenium-type carbon to form carbon–hydrogen bond with the formation of C(sp^2)–H bond to afford the product 2a.

(b) 

(c) The scope of the present hydrogenolysis is summarized in Table 2. The secondary benzocyclobutenyl ethers 1e and 1f underwent hydrogenolysis of the C–C σ-bond to give the ring-opening products 2e and 2f together with the arene-hydrogenated products 3e and 3f (entries 1 and 2). Reaction of the isopropyl-substituted benzocyclobutene 1g

Scheme 3. A possible reaction mechanism

The scope of the present hydrogenolysis is summarized in Table 2. The secondary benzocyclobutenyl ethers 1e and 1f underwent hydrogenolysis of the C–C σ-bond to give the ring-opening products 2e and 2f together with the arene-hydrogenated products 3e and 3f (entries 1 and 2). Reaction of the isopropyl-substituted benzocyclobutene 1g
afforded ring-opening product 2g selectively (entry 3). The isopropyl ether 1h underwent efficient hydrogenolysis of the C–C α-bond to give 2h exclusively. Although cyclopropyl group substituted substrate 1i also gave the C–C bond cleavage product 2i in 25% yield, hydrogenolysis of cyclopropane moiety was competed to generate 2i' (entry 5). Whereas introduction of a methoxy group at the 6-position of benzocyclobutene ring accelerated hydrogenation of the arene ring, introduction of trifluoromethyl group at the same position reduced the amount of the arene-hydrogenated product (entries 6 and 7). The substrate bearing benzyl ether moiety 1l could be applied for this reaction. Hydrogenolysis of the C–C bond took place more rapidly than that of the benzylic C–O bond (entry 8). The reaction of methoxybenzocyclobutene possessing a phenyl group at R^3 position 1m gave the corresponding product 2m in 21% yield with the generation of bibenzyl 2m' (entry 9). When methoxybenzocyclobutene as a single diastereomer 1n was utilized to this reaction condition, the corresponding product 2n was obtained in 75% yield as a diastereomeric mixture (dr = 68:32) (entry 10). 1-Phenyl-substituted benzocyclobutene 1q underwent hydrogenolysis very slowly to afford 2q (entry 13).

<sup>a</sup> Reaction conditions: alkoxybenzocyclobutene 1 (0.20 mmol), palladium on carbon (5 mol % Pd), MS 4A (20.0 mg), dichloromethane (3.0 mL), rt, 24 h unless otherwise noted. <sup>b</sup> Isolated yields. <sup>c</sup> Palladium on carbon (10 mol % Pd), MS 4A (30.0 mg) <sup>d</sup>NMR yield. <sup>e</sup> The reaction was performed in MeOH without MS 4A.

**Conclusions**

1-alkoxybenzocyclobutenes undergo hydrogenolysis with site-selective cleavage of the sterically more hindered C(sp<sup>2</sup>)–C(sp<sup>3</sup>) bond. The benzylic C–O σ-bond and the other C(sp<sup>3</sup>)–C(sp<sup>3</sup>) bonds including sterically more accessible ones remain intact under the present reaction conditions.
Experimental section

General. All reactions were carried out in oven-dried glassware with standard Schlenk techniques unless otherwise noted. Flash column chromatography was performed with silica gel 60 N (Kanto). Preparative thin-layer chromatography was performed on silica gel plates with PF254 indicator (Merck). Infrared spectra were recorded on a Shimadzu FTIR DR-8000 spectrometer. $^1$H and $^{13}$C NMR spectra were recorded on a Varian Mercury vx400 ($^1$H at 400 MHz and $^{13}$C at 100 MHz) spectrometer using CDCl$_3$ ($^1$H, δ = 7.26) and CDCl$_3$ ($^{13}$C, δ = 77.0) as an internal standard unless otherwise noted. High-resolution mass spectra were recorded on a Thermofisher EXACTIVE (APCI). Gel permeation chromatography was carried out with a Japan Analytical Industry LC-9210II NEXT.

Materials. Anhydrous DCM and THF were purchased from Kanto Chemical Co. The following compounds were synthesized according to the literature procedures; benzocyclobutenone,$^{11a}$ methoxybenzocyclobutenone,$^{11a}$ 6-trifluoromethylbenzocyclobutenone,$^{11b}$ 6-benzyloxybenzocyclobutenone,$^{11c}$ 2-ethyl-1-methylbenzocyclobutene,$^{11d}$ 1-tert-butyldimethylsiloxybenzocyclobutene 1d,$^{11e}$ and 1-phenylbenzocyclobutene 1k.$^{11d}$ All other commercially available chemical resources were used as received without further purification.

General procedure for the synthesis of benzocyclobutenols

To a stirred solution of benzocyclobutenone (1.0 equiv) in THF (3 mL/mmol) was added n-BuLi (hexane solution, 1.6 M, 1.2 equiv) slowly at $-78$ °C. After stirring for 1 h at $-78$ °C, saturated NH$_4$Cl aq was added. The mixture was extracted with Et$_2$O, washed with water and brine, dried over MgSO$_4$ and evaporated. After purification by chromatography on silica gel, the corresponding benzocyclobutene was obtained.

**General procedure for the synthesis of alkoxybenzocyclobutene**

![Chemical Structure](image)

A mixture containing benzocyclobutenol (1.0 equiv), Ag\(_2\)O (1.05 equiv), MeI (5.0 equiv) and acetone (1 ml/mmol of benzocyclobutenol) was stirred at 65 °C under air. The reaction mixture was filtered through a celite pad and concentrated. The residue was purified by column chromatography on silica gel or gel permeation chromatography to yield methoxybenzocyclobutene.

Found m/z 177.1269; The stereochemistry was determined by the analysis of NOE.

**Synthesis of Acetoxybenzocyclobutene 1c**

![Chemical structure of S1](image)

To a stirred solution of benzocyclobutenol S1 (126 mg, 0.72 mmol) in THF (3.0 mL) was added n-BuLi (hexane solution, 1.6 M, 0.54 mL, 0.87 mmol) slowly at −78 °C. After stirring for 20 min at −78 °C, Ac₂O (250 mg, 2.5 mmol) in THF (2.0 mL) was added dropwise to a reaction mixture. The obtained solution was stirred at rt for 2 h and then saturated NH₄Cl aq was added. The mixture was extracted with Et₂O, washed with water and brine, dried over MgSO₄, and evaporated. After purification by chromatography on silica gel (hexane/ethyl acetate = 20/1), the desired product 1c was obtained in 29% yield; IR (neat): 2957, 1734, 1236, 1020, 714 cm⁻¹; ¹H NMR: δ = 0.89 (t, J = 6.8 Hz, 3H), 1.24–1.46 (m, 4H), 2.02–2.14 (m, 1H), 2.05 (s, 3H), 2.20–2.32 (m, 1H), 3.36 (d, J = 14.0 Hz, 1H), 3.42 (d, J = 14.4 Hz, 1H), 7.15 (d, J = 7.2 Hz, 1H), 7.20–7.26 (m, 1H), 7.27–7.33 (m, 1H), 7.35 (d, J = 7.2 Hz, 1H); ¹³C NMR: δ = 14.0, 21.6, 22.8, 26.8, 34.9, 43.5, 85.9, 123.4, 123.8, 127.1, 129.6, 141.7, 146.9, 170.4; HRMS (APCI): Calcd for C₁₄H₁₉O₂, [M+H]⁺ 219.1380. Found m/z 219.1376.

**General procedure for a Pd/C-catalyzed reaction of alkoxybenzocyclobutenes**

![Chemical structure of R₁OR₂](image)

To the schlenk equipped with a stirrer bar were added 10 wt. % dried Pd/C (10.6 mg, 0.010 mmol, 5 mol % Pd) and MS 4A (20.0 mg) under argon atmosphere. The alkoxybenzocyclobutene (0.20 mmol) in DCM (3.0 mL) was added to the flask. After the argon gas was replaced with hydrogen gas, the solution was stirred at room temperature. The reaction mixture was filtered through a celite pad and concentrated. The residue was purified by preparative thin-layer chromatography or gel permeation chromatography to yield the ring-opening product.

2l:

![Structure Image]

Purified by gel permeation chromatography; IR (neat): 2928, 1582, 1258, 1094, 694 cm$^{-1}$; $^1$H NMR: $\delta = 0.88 \text{ (t, } J = 7.2 \text{ Hz, 3H)}$, $1.22–1.50 \text{ (m, 6H)}$, $2.66 \text{ (dd, } J = 13.6, 6.4 \text{ Hz, 1H)}$, $2.82 \text{ (dd, } J = 13.6, 6.4 \text{ Hz, 1H)}$, $3.31 \text{ (s, 3H)}$, $3.34 \text{ (dddd, } J = 12.0, 12.0, 6.0,$
6.0 (1H), 5.06 (s, 2H), 6.79–6.86 (m, 2H), 6.85 (s, 1H), 7.20 (dd, $J = 7.6$, 7.6 Hz, 1H), 7.30–7.36 (m, 1H), 7.39 (dd, $J = 7.2$, 7.2 Hz, 2H), 7.44 (d, $J = 7.2$ Hz, 2H); $^{13}$C NMR: $\delta$ = 14.1, 22.8, 27.5, 33.3, 40.2, 57.0, 69.9, 82.3, 112.2, 116.1, 122.1, 127.5, 127.9, 128.5, 129.2, 137.1, 140.9, 158.7.

$^{3c}$:

\[
\text{OAc} \quad \text{n-Bu}
\]

Purified by gel permeation chromatography; IR (neat): 2928, 1732, 1254, 1016 cm$^{-1}$; $^1$H NMR: $\delta$ = 0.88 (t, $J = 7.2$ Hz, 3H), 0.89 (t, $J = 7.2$ Hz, 3H*), 1.08–1.36 (m, 7H + 7H*), 1.41–1.54 (m, 2H + 2H*), 1.57–1.89 (m, 5H + 5H*), 1.98 (s, 3H*), 1.99 (s, 3H), 2.08–2.17 (m, 1H + 1H*), 2.21–2.29 (m, 1H + 1H*), 2.32–3.42 (m, 1H + 1H*), 2.48–2.56 (m, 1H + 1H*); $^{13}$C NMR: $\delta$ = 14.1, 14.1*, 21.4*, 21.6*, 21.9, 22.0*, 22.1, 22.2, 22.3, 22.6*, 22.9*, 22.9, 25.4, 25.69*, 25.73*, 26.1*, 26.1, 27.6, 33.1*, 34.7*, 34.9*, 36.8, 42.0, 42.6*, 81.0*, 87.0, 169.9*, 170.2; HRMS (APCI): Calcd for C$_{14}$H$_{25}$O$_2$Na, [M+H]$^+$ 225.1849. Found m/z 225.1845.

List of Publications

Chapter 1

Synthesis of 3,3-disubstituted α-tetralones by rhodium-catalysed reaction of 1-(2-haloaryl)cyclobutanols
Naoki Ishida, Shota Sawano, Masahiro Murakami

Chapter 2

Rhodium-Catalyzed Ring Opening of Benzocyclobutenols with Site-Selectivity Complementary to Thermal Ring Opening
Naoki Ishida, Shota Sawano, Yusuke Masuda, Masahiro Murakami

Chapter 3

Construction of tetralin skeletons based on rhodium-catalysed site-selective ring opening of benzocyclobutenols
Naoki Ishida, Norikazu Ishikawa, Shota Sawano, Yusuke Masuda, Masahiro Murakami

Chapter 4

Stereospecific ring expansion from orthocyclophanes with central chirality to metacyclophanes with planar chirality
Naoki Ishida, Shota Sawano, Masahiro Murakami

Chapter 5

Ring Opening of Alkoxycyclobutenes with Site-Selective Hydrogenolysis of C(sp^2^)–C(sp^3^) Bond
Shota Sawano, Naoki Ishida, Masahiro Murakami
