Running title: Mitochondrial TRPV1 in microglial migration
Main points: Activation of TRPV1 triggers an increase in intramitochondrial Ca²⁺ concentration and following depolarization of mitochondria, which results in mtROS production, MAPK activation, and enhancement of chemotactic activity in microglia.
Abstract
Microglia, the resident immune cells in the brain, survey the environment of the healthy brain. Microglial migration is essential for many physiological and pathophysiological processes. Although microglia express some members of the transient receptor potential (TRP) channel family, there is little knowledge regarding the physiological roles of TRP channels in microglia. Here, we explored the role of TRP vanilloid 1 (TRPV1), a channel opened by capsaicin, heat, protons, and endovanilloids, in microglia. We found that application of capsaicin induced concentration-dependent migration in microglia derived from wild-type mice but not in those derived from TRPV1 knock-out (TRPV1-KO) mice. Capsaicin-induced microglial migration was significantly inhibited by co-application of the TRPV1 blocker SB366791 and the Ca²⁺ chelator BAPTA-AM. Using RT-PCR and immunocytochemistry, we validated that TRPV1 was expressed in microglia. Electrophysiological recording, intracellular Ca²⁺ imaging and immunocytochemistry indicated that TRPV1 was localized primarily in intracellular organelles. Treatment with capsaicin induced an increase in intramitochondrial Ca²⁺ concentrations and mitochondrial depolarization. Furthermore, microglia derived from TRPV1-KO mice showed delayed Ca²⁺ efflux compared with microglia derived from wild-type mice. Capsaicin-induced microglial migration was inhibited by membrane-permeable antioxidants and MAPK inhibitors, suggesting that mitochondrial TRPV1 activation induced Ca²⁺-dependent production of ROS followed by MAPK activation, which correlated with an augmented migration of microglia. Moreover, a mixture of three endovanilloids augmented microglial migration via TRPV1 activation. Together, these results indicate that mitochondrial TRPV1 plays an important role in inducing microglial migration.

Key words: Microglia, Cell movement, TRPV1, Mitochondria, Ca²⁺ signaling.

Introduction
Microglia are endogenous resident immunocompetent cells in the CNS (Kettenmann et al., 2011). Microglial migration is essential for many physiological and pathophysiological processes. The amounts of many kinds of chemotactic molecules are regulated by physiological and pathological factors. For example, ATP, which is known to act as a neurotransmitter or a signaling molecule involved in cell death, activates microglial P2Y₁₂ and P2X₄ receptors and induces chemotaxis through PI3K activation (Honda et al., 2001; Ohsawa et al., 2007). Glutamate, one of the most ubiquitous neurotransmitters in the brain, stimulates microglial chemotactic activity via AMPA receptor and mGluR activation (Liu et al., 2009). The well-known chemokine CX3CL1 (fractalkine) is expressed by neurons in the CNS and modulates microglial behavior to find injured neurons (Cardona et al., 2006; Liang et al., 2009). Microglial behavior is also regulated by cation channels, such as Nav1.6 (Black et al., 2009), Kir2.1 (Muessel et al., 2013) and acid-sensing ion channel (Yu et al., 2015). Although a large number of studies demonstrate how microglial chemotactic activity is regulated, the mechanism is not yet completely
understood.

Transient receptor potential vanilloid 1 (TRPV1) is one of the most well-characterized sensory channels in the TRP channel superfamily (Wu et al., 2010). TRPV1 is expressed in somatosensory neurons and is opened by capsaicin, heat, protons (Caterina et al., 1997; Tominaga et al., 1998), and endovanilloids (Zygmunt et al., 1999). Recent studies reveal that TRPV1 is functionally expressed not only on the plasma membrane but also in intracellular organelles, such as the endoplasmic reticulum (ER) (Gallego-Sandín et al., 2009), sarcoplasmic reticulum (Ito et al., 2013), Golgi apparatus (Turner et al., 2003) and mitochondria (Lang et al., 2014). TRPV1 is expressed not only in neurons but also in astrocytes (Mannari et al., 2013; Ho et al., 2014) and immune cells, such as monocytes (Schilling et al., 2009), macrophages (Fernandes et al., 2012), dendritic cells (Basu et al., 2005), and T cells (Bertin et al., 2014).

Microglia express several types of TRP channels. For instance, activation of the TRPV4 channel attenuates the driving force of extracellular Ca\(^{2+}\) and suppresses microglial activation (Konno et al., 2012). Lipopolysaccharide (LPS) and IFN\(\gamma\) activate TRPM2-mediated Ca\(^{2+}\) signaling, which in turn increases downstream p38 MAPK and JNK signaling and results in increased nitric oxide (NO) production (Miyake et al., 2014). Brain-derived neurotropic factor (BDNF) induces sustained intracellular Ca\(^{2+}\) elevation through the upregulation of surface TRPC3 channels, and TRPC3 channels contribute to the BDNF-induced suppression of NO production (Mizoguchi et al., 2014). Some reports also indicate that microglia express functional TRPV1, and its activation causes cell death (Kim et al., 2006), promotes phagocytosis (Hassan et al., 2014), ROS generation (Schilling et al., 2011; Park et al., 2012), and cytokine production (Sappington et al., 2008). However, other contributions of TRPV1 to microglial physiological functions remain unknown. Although TRPV1 blockade inhibits LPC-induced migration in monocytes (Schilling et al., 2009) and TRPV1 activation directly induces migration in dendritic cells (Basu et al., 2005), the molecular details by which TRPV1 activation induces cell migration is still unclear. Here, we demonstrate that TRPV1 contributes to microglial migration using TRPV1 knock-out (TRPV1-KO) mice. The effects of endovanilloids, physiological agonist candidates of TRPV1, were also examined.

**Materials and Methods**

**Animals**

All experiments were conducted in accordance with the ethical guidelines of the Kyoto University Animal Research Committee. TRPV1-KO mice were a gift from Dr. David Julius (University of California, San Francisco). The mice were maintained at a constant ambient temperature of 24 ± 1°C under a 12 h light/dark cycle with free access to food and water.

**Mouse primary cultured microglia**

Primary microglial cultures were prepared from newborn wild-type (WT) and TRPV1-KO mice (1–2 days old). Dissociated cells were seeded on 75 cm\(^2\) flasks in Dulbecco’s modified Eagle’s medium (DMEM, D5796, Life Technologies, Carlsbad,
CA) supplemented with 10% heat-inactivated FBS, 5 µg/mL insulin (Sigma, St. Louis, MO) and a 1% penicillin/streptomycin mixed solution (Nacalai Tesque, Kyoto, Japan) and maintained at 37°C in a humidified 5% CO₂ atmosphere. After 2–3 weeks, the primary mixed glial cultures in flasks were shaken for 90 min at 150 rpm. The detached cells were plated on 35-mm dishes (1.0 × 10⁶ cells/dish), or cover glasses (10 mm diameter, 5 × 10⁴ cells/glass) for each experiment and used within 3 days.

**Cell line culture and transfection**

Human embryonic kidney-derived 293T (HEK293T) cells were cultured in DMEM modified with GlutaMAX (10566-016, Life Technologies) containing 10% heat-inactivated FBS and maintained at 37°C in a humidified 5% CO₂ atmosphere. For electrophysiological experiments, HEK293T cells in 35 mm dishes were transfected with 2.56 µg of pCIneo-rTRPV1 and 0.64 µg of pEGFP-C3 using 4 µL of Lipofectamine 2000 reagent (Life Technologies) in 1 mL of Opti-MEM (Life Technologies) for 4–5 h at 37°C in a humidified 5% CO₂ atmosphere. After the transfection, the medium was changed to 2 mL of culture medium. After 1–2 days, the cells were removed from the dish using a solution containing 0.05% trypsin and 0.53 mM EDTA (Nacalai Tesque), collected with centrifugation, resuspended in culture medium and attached to coverslips that were pretreated with poly-L-lysine (Sigma). For confocal microscopy, HEK293T cells stably expressing rTRPV1 channel were used as described above (except for the transfection process).

**Measurement of NO accumulation**

The NO production was analyzed by measuring the accumulated level of its stable metabolite (nitrite) in the culture media with the Griess reaction. Culture medium (40 µL) was added to 96-well plates and mixed with an equal volume of Griess reagent (1% sulfanilamide, 2.5% phosphoric acid, and 0.1% naphthylethlenediamine dihydrochloride) for 10 min at room temperature. The absorbance of the diazonium compound was measured at 540 nm using a microplate reader (Model 680; Bio-Rad). The absolute levels of nitrite were determined with reference to a standard curve obtained from defined concentrations of sodium nitrite (Sigma).

**ELISA**

The levels of TNF-α and IL-6 in the culture media were determined using mouse TNF-α and IL-6 ELISA kits (R & D Systems, Minneapolis, MN) in accordance with the manufacturer’s protocols. Culture medium suspected of having levels of cytokines/chemokines above the linear range of the standard curve was diluted appropriately in accordance with the manufacturer’s protocols. Every sample was assayed in duplicate in the same plate. Absorbance was measured using a microplate reader (Model 680; Bio-Rad, Hercules, CA).

**Confocal microscopy**

Cells on coverslips were fixed with 4% PFA and then permeabilized with PBS containing 3% BSA and 0.1% Triton X-100 for 15 min. For TRPV1 detection, cells
were incubated with rabbit polyclonal anti-TRPV1 (1:200; Alomone Labs, Jerusalem, Israel) for 3 h at room temperature, followed by incubation with the Alexa Fluor 594-conjugated donkey anti-rabbit secondary antibody (1:200; Life Technologies) for 1.5 h at room temperature. For detection of subcellular organelles, cells were incubated overnight at 4°C with rat monoclonal anti-mouse LAMP1 (1:100; eBioscience, San Diego, CA), goat polyclonal anti-58K Golgi protein (1:50; Abcam, Cambridge, MA), and goat polyclonal anti-calregulin (1:50; Santa Cruz, Dallas, TX) along with anti-TRPV1 antibody, and then incubated with Alexa Fluor 488-conjugated goat anti-rat or donkey anti-goat secondary antibodies (1:20,000 or 1:200, respectively; Life Technologies) or with Alexa Fluor 594-conjugated donkey anti-rabbit secondary antibody (1:200; Life Technologies) for 1.5 h at room temperature. For detection of mitochondria, living cells on coverslips were incubated in Krebs-Ringer buffer (which contained the following, in mM: 140 NaCl, 5 KCl, 1 MgCl₂, 2 CaCl₂, 10 HEPES, and 10 D-glucose, adjusted to pH 7.4 with NaOH) with MitoTracker Red (Molecular Probes, Eugene, OR) (1 µM) for 40 min at 37°C in a humidified 5% CO₂ atmosphere. Cells were rinsed twice with Krebs-Ringer buffer, fixed, permeabilized, and then incubated with rabbit polyclonal anti-TRPV1 (1:200) for 3 h at room temperature, followed by incubation with the Alexa Fluor 488-conjugated donkey anti-rabbit secondary antibody (1:200; Life Technologies) for 1.5 h at room temperature. To detect membrane ruffling, fixed cells were incubated with the Alexa Fluor 488-conjugated phalloidin (1:200; Life Technologies) for 1 h at room temperature as previously described (Shirakawa et al., 2010). After mounting the coverslips in the anti-fading medium Vectashield or Vectashield with DAPI (Vector Laboratories, Burlingame, CA), the fluorescence immunoimages were acquired with a FluoView FV10i confocal laser-scanning microscope (Olympus, Tokyo Japan).

**Electrophysiology**

Whole-cell currents were recorded at room temperature with a pipette made from a 1.5-mm outer-diameter glass capillary with a filament (Narishige, Tokyo, Japan) and pulled using a P-87 micropipette puller (Sutter, Novato, CA). The access resistance ranged from 2 to 5 MΩ when the pipette was filled with the intracellular solution described below. The extracellular and intracellular solution contained (in mM) 140 NaCl, 5 KCl, 2 MgCl₂, 2 EGTA, 10 HEPES, and 10 D-glucose (adjusted to pH 7.4 with NaOH). Current-voltage relationships were measured using voltage ramps (−100 to +100 mV over 200 ms, 0.5 Hz). The holding potential was set at 0 mV. Access resistances were compensated by 70%. Patch-clamp recordings were performed using an EPC-10 patch-clamp amplifier (HEKA Instruments, Lambrecht, Germany) and PATCHMASTER software (HEKA). All perfusions were performed with a VC-6 perfusion system (Warner Instruments, Hamden, CT). For analysis, data were filtered at 2.9 kHz.

**Measurement of intracellular Ca^{2+} concentration**

Time-lapse imaging of intracellular Ca^{2+} concentration was examined with the Ca^{2+}-sensitive fluorescent dye Fura-2 acetoxymethyl ester (Fura-2 AM; Dojindo Laboratory, Kumamoto, Japan) using a fluorescence imaging system.
(AQUACOSMOS image acquisition software with an ORCA-R2 CCD camera, Hamamatsu Photonics, Shizuoka, Japan). Cells were incubated in Krebs-Ringer buffer containing 5 µM Fura-2 AM and 0.005% Cremophore EL (Sigma) for 40 min at 37°C in a humidified 5% CO₂ atmosphere. After rinsing with the buffer, the cells were transferred to a recording chamber on the stage of an IX71 inverted fluorescence microscope (Olympus). The Fura-2 fluorescence obtained by excitation wavelengths of 340 nm and 380 nm and emission wavelengths of 500 nm was recorded at 2 s intervals at room temperature. Capsaicin perfusion was performed with a VC-6 perfusion system (Warner Instruments). Additional drug solutions were perfused into the recording chamber. The rate of Ca²⁺ influx or efflux was obtained by measuring the initial slope of Ca²⁺ rise or decline, respectively. The maximal value of the normalized fluorescence intensity was taken as the peak amplitude or influx. The width of the peak at its half-amplitude (t₁/₂) was determined to evaluate the response time.

**Measurement of intramitochondrial Ca²⁺ concentration**

Time-lapse imaging of intramitochondrial Ca²⁺ concentration was estimated with the cationic Ca²⁺-sensitive fluorescent dye Rhod-5N acetoxymethyl ester (Rhod-5N AM; AAT Bioquest, Sunnyvale, CA) using an A1R MP+ multiphoton confocal microscope (Nikon) and NIS-Elements C acquisition and analysis software (Nikon). Cells on a 35-mm glass-bottom dish were incubated in recording buffer (which contained, in mM, 120 NaCl, 6 KCl, 2 MgCl₂, 0.3 CaCl₂, 10 HEPES, 12 D-glucose, and 12 sucrose, adjusted to pH 7.4 with NaOH) with 5 µM Rhod-5N AM and 0.005% Cremophore EL (Sigma) for 50 min at 37°C in a humidified 5% CO₂ atmosphere. After rinsing with the buffer, Rhod-5N fluorescence obtained by excitation wavelengths of 551 nm and emission wavelengths of 576 nm was recorded at 6 s intervals at room temperature. Drug solutions were applied by perfusion to the recording chamber.

**Mitochondrial membrane potential assay**

The mitochondrial membrane potential (mΔΨ) was determined with a JC-1 mitochondrial membrane potential assay kit (Cayman, Ann Arbor, MI). Cells on a glass-bottom dish were treated with drugs for 24 h. The JC-1 dye in culture medium was added to the cell culture and incubated for 30 min at 37°C in a humidified 5% CO₂ atmosphere. Microscopy was performed using a FluoView FV10i confocal laser-scanning microscope (Olympus). Images were captured in five randomly selected microscopic fields for each treatment by an investigator who was blind to the experimental conditions. The ratio of the fluorescent intensity obtained by the excitation/emission of 578/599 nm (F₅₇₈) to the fluorescent intensity obtained by the excitation/emission of 485/535 nm (F₄₈₅), namely F₅₇₈/F₄₈₅, was calculated to quantitate mΔΨ.

**Scratch-wound assay**

Microglia were plated in a 35-mm dish. After 1 day, cell cultures were scratched with a 1000 µL sterile pipette tip. After one wash with culture medium, cells were maintained at 37°C in a humidified 5% CO₂ atmosphere. Phase contrast images of
the wounds were acquired at 0 h and 24 h after scratching using a TE300 inverted fluorescence microscope (Nikon) and a DS-5Mc-L2 digital camera system (Nikon).

**Chemotactic assay**

The chemotactic assay was performed with transwell-based Chemotaxicell chambers having a 5-µm pore size (Kurabo, Osaka, Japan). Microglia were planted in the upper chamber or chamber-free blank well at a density of 5.0 × 10^5 cells per well. All drugs were added to the lower chamber or chamber-free well. Cells were allowed to migrate for 24 h at 37°C in a humidified 5% CO2 atmosphere. The cells that migrated to the bottom of the lower chamber or chamber-free well were examined and captured in two representative microscopic fields by an investigator who was blind to the experimental conditions (each treatment was performed in duplicate chamber-placed wells and one chamber-free well), and the cell numbers in each individual field were counted. The chemotactic ratio was calculated by dividing the cell number of the lower chamber by the cell number of the chamber-free well.

**Statistical analyses**

All data are expressed as means ± SEM. Statistical analyses were performed using Student’s *t*-tests, one-way ANOVA followed by Tukey’s multiple comparisons tests, and two-way ANOVA followed by Bonferroni post-hoc tests using GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA). Probability values less than 5% (*p* < 0.05) were considered significant.

**Results**

**Capsaicin induces microglial chemotactic activity**

To explore the physiological role of TRPV1 in microglia, we assessed whether capsaicin affected microglial chemotactic activity using a Boyden chamber assay (Walter et al., 2003). Capsaicin (1–10 µM) augmented the chemotactic activity of microglia derived from WT mice in a concentration-dependent manner (Fig. 1A), and this augmentation was significantly inhibited by co-treatment with SB366791 (3 µM), a TRPV1 selective blocker (Fig. 1A). By contrast, microglia derived from TRPV1-KO mice showed no change in chemotactic activity after application of capsaicin (Fig. 1B). To investigate the contribution of Ca^{2+}, we simultaneously applied capsaicin with BAPTA-AM (10 µM), an intracellular Ca^{2+} chelator. The BAPTA-AM significantly suppressed the capsaicin-induced chemotaxis in microglia derived from WT mice (Fig. 1A), but not in microglia derived from TRPV1-KO mice (Fig. 1B). All the treatments did not affect cell viability (Supplementary figure 1 and 2), and SB366791 and BAPTA-AM alone did not affect the basal microglial cell migration (Supplementary figure 3).

To confirm the effect of capsaicin on microglial chemotactic activity, we performed a scratch-wound assay (Siddiqui et al., 2012). Treatment with capsaicin (10 µM) for 24 h increased the number of the microglia populating a cell-free area (Fig. 1C). Next, we investigated the effect of capsaicin on microglial membrane ruffling (Honda et al., 2001). Phalloidin staining demonstrated that 10 µM capsaicin stimulation for 24 h caused membrane ruffling in microglia derived from WT mice.
(Fig. 1D, white arrow). Co-treatment of microglia with SB366791 (3 µM), a selective TRPV1 blocker, inhibited the capsaicin-induced membrane ruffling (Fig. 1D). By contrast, microglia derived from TRPV1-KO mice showed no capsaicin-induced membrane ruffling (Fig. 1E).

**Activation of TRPV1 is not involved in other cellular functions**
To exclude any unanticipated effects of TRPV1 deletion on microglial chemotactic activity, we investigated ATP-induced chemotaxis in microglia. Treatment with ATP (100 µM) for 24 h induced robust chemotactic activity in microglia derived from both WT (Fig. 2A) and TRPV1-KO mice (Fig. 2B), indicating that ATP-induced chemotaxis is independent of TRPV1 activation. Furthermore, TRPV1 activation with capsaicin followed by combined treatment with LPS (100 ng/mL) and IFNγ (10 ng/mL) for 48 h had no effect on the production of NO (Figs. 2C and 2D, and Supplementary figure 4), TNF-α (Figs. 2E and 2F), and IL-6 (Figs. 2G and 2H) in microglia, although capsaicin administration enhanced TNF-α release in a TRPV1-independent manner by unknown mechanisms (Figs. 2E and 2F). These data indicate that activation of TRPV1 has little effect on other cellular functions such as ATP-induced chemotaxis and the release of inflammatory molecules in microglia.

**TRPV1 is expressed in intracellular organelles in cultured mouse microglia**
To determine whether murine-cultured microglia expressed TRPV1, we examined the expression of TRPV1 using immunohistochemistry and revealed that TRPV1 channels in HEK293T cells that were stably expressing these channels were located on the plasma membrane (Fig. 3A), whereas microglia derived from WT mice exhibited a punctate cytoplasmic distribution of TRPV1 channels (Fig. 3A). By contrast, no immunoreactivity was observed in microglia derived from TRPV1-KO mice (Fig. 3A). Presumably, ~60% of microglia expressed detectable TRPV1 immunoreactivity (Fig. 3B). These results indicate that TRPV1 is expressed in a large population of microglia and likely located in intracellular organelles rather than on the plasma membrane.

To determine the intracellular localization of TRPV1 in microglia, we performed co-immunostaining of TRPV1 and intracellular organelles. Analysis using confocal microscopy revealed that TRPV1 showed co-localization with the ER marker calregulin, the Golgi marker 58K Golgi protein, the lysosomal marker lysosomal-associated membrane protein 1 (Lamp1) and the mitochondrial marker MitoTracker Red (Fig. 3C). These results indicate that TRPV1 is expressed in intracellular organelles in microglia.

**TRPV1 regulates mitochondrial Ca²⁺ uptake in microglia**
To confirm that the TRPV1 channel was not present in the plasma membrane in microglia, we assessed TRPV1 expression directly using whole-cell patch-clamp recordings. Whereas HEK293T cells transiently expressing rat TRPV1 showed strong, concentration-dependent capsaicin-evoked currents (Fig. 4A), microglia showed no capsaicin-evoked current (Fig. 4B). Capsaicin (10 µM) subtly inhibited
the inward current in microglia, although this inhibition was not blocked by co-application of SB366791 (3 µM) (data not shown). This observed capsaicin-induced inhibition of inward currents might be attributed to the inhibitory effect of capsaicin on potassium currents (Kuenzi et al., 1996). To address the possibility that TRPV1 channel is located in intracellular organelles and activation of TRPV1 contributes to increases in intracellular Ca²⁺ concentration, we examined the effect of capsaicin on microglial intracellular Ca²⁺ concentration using the high affinity Ca²⁺ indicator Fura-2 AM. No response to capsaicin was observed in microglia (Fig. 4C). Taken together, these results suggest that TRPV1 is not located on the plasma membrane and that TRPV1 stimulation does not contribute to the Ca²⁺ influx across the plasma membrane or to the Ca²⁺ release from intracellular stores.

Mitochondria are involved in Ca²⁺ buffering, and this mitochondrial Ca²⁺ signaling has a role in controlling cell metabolism, cell-type specific functions and cell survival (Rizzuto et al., 2012). To investigate the effect of TRPV1 activation on mitochondria, we performed intramitochondrial Ca²⁺ imaging using the low affinity cationic Ca²⁺ indicator Rhod-5N AM. Capsaicin (10 µM) evoked an increase of the intramitochondrial Ca²⁺ concentration in microglia derived from WT mice, but this effect was significantly suppressed in microglia derived from TRPV1-KO mice (Figs. 4D and 4E). To explore the involvement of TRPV1 in mitochondrial Ca²⁺ buffering, we observed the ATP-induced store-operated Ca²⁺ entry (SOCE) in microglia derived from both WT and TRPV1-KO mice. Although the amplitude of the SOCE was similar in both genotypes (Figs. 4F and 4G), the time to half-amplitude (t₁/₂) was significantly prolonged in microglia derived from TRPV1-KO mice compared with that in microglia derived from WT mice (Figs. 4F and 4H). Furthermore, blockade of TRPV1 with SB366791 (3 µM) significantly prolonged the t₁/₂, but did not change the amplitude of ATP-induced SOCE, similar to microglia derived from TRPV1-KO mice (Figs. 4F-H). The influence of TRPV1 activation on the mΔΨ was also investigated using JC-1 dye. Treatment with capsaicin (10 µM) for 24 h showed a significant decrease in the mΔΨ in microglia derived from WT mice, and this decrease was blocked by the co-administration of SB366791 (3 µM) (Fig. 4I). No change in the mΔΨ was observed in microglia derived from TRPV1-KO mice (Fig. 4J). These results suggest that activation of TRPV1 evokes a Ca²⁺ influx into mitochondria, followed by mitochondrial depolarization in microglia.

**TRPV1 activation enhances microglial chemotactic activity via mitochondrial ROS production followed by p38 MAPK and JNK activation**

To determine the role of mitochondria in capsaicin-induced chemotaxis (as shown in Fig. 1), we investigated the effect of rotenone, a specific inhibitor of mitochondrial electron transport complex I, using the Boyden chamber assay. Although rotenone (0.3 µM) co-treatment had no effect on the ATP-induced chemotaxis, rotenone significantly inhibited the capsaicin-induced chemotaxis (Fig. 5A). Mitochondrial Ca²⁺ uptake induces mitochondrial depolarization, resulting in generation of ROS (Brookes et al., 2004; Ferraiuolo et al., 2011; Takeuchi et al., 2014). Because capsaicin treatment induced TRPV1-dependent mitochondrial
depolarization in microglia (Figs. 4I and 4J), we assessed the effects of various antioxidants on capsaicin-induced chemotaxis to examine the involvement of mitochondrial ROS (mtROS). The membrane-permeable antioxidants EUK-134 (3 \( \mu \)M), Mn-TBAP (30 \( \mu \)M) and TEMPOL (1 mM) significantly inhibited microglial chemotaxis, whereas the membrane-impermeable antioxidants glutathione (1 mM) and vitamin C (100 \( \mu \)M) showed no significant effects (Fig. 5B), suggesting that intracellular ROS have an important role in capsaicin-induced chemotaxis. These results indicate that capsaicin induces microglial chemotaxis through mtROS generation.

To confirm whether ROS induced microglial chemotaxis, we investigated the effect of hydrogen peroxide (H\(_2\)O\(_2\)) on microglial chemotactic activity. Hydrogen peroxide (10 \( \mu \)M) significantly induced chemotaxis in microglia derived from WT mice (Fig. 5C), but this chemotaxis was not blocked by the TRPV1 blocker SB366791 (3 \( \mu \)M) (Fig. 5C) and was also observed in microglia derived from TRPV1-KO mice (Fig. 5D), suggesting that this H\(_2\)O\(_2\)-induced chemotaxis is TRPV1-independent. Furthermore, the H\(_2\)O\(_2\)-induced chemotaxis was significantly inhibited by EUK-134 (3 \( \mu \)M) in microglia derived from both WT (Fig. 5C) and TRPV1-KO mice (Fig. 5D). To unravel the downstream signaling of this phenomenon, we examined the effect of a MAPK inhibitor on the H\(_2\)O\(_2\)-induced chemotaxis. Whereas the ERK inhibitor PD98059 (10 \( \mu \)M) had no effect on the H\(_2\)O\(_2\)-induced chemotaxis, the p38 MAPK inhibitor SB203580 (30 \( \mu \)M) and the JNK inhibitor SP600125 (30 \( \mu \)M) significantly inhibited the H\(_2\)O\(_2\)-induced chemotaxis (Fig. 5C). Similarly, the capsaicin-induced chemotaxis was also significantly inhibited by SB203580 (30 \( \mu \)M) and SP600125 (30 \( \mu \)M), but not by PD98059 (10 \( \mu \)M) (Fig. 5E). All the inhibitors did not affect the cell viability (Supplementary figure 1 and 2) and basal microglial cell migration (Supplementary figure 3). These results suggest that the mtROS induced by capsaicin treatment triggers microglial chemotaxis via activation of p38 MAPK and JNK.

**Endovanilloids induce microglial chemotaxis via a TRPV1-dependent mechanism**

Our search for an endogenous TRPV1 agonist focused on endovanilloids because they are released in physiological (Maccarrone et al., 2008; Tanimura et al., 2010) and pathological (Franklin et al., 2003; Stock et al., 2012) conditions in the brain. We investigated the effect of three endovanilloids, arachidonylethanolamide (AEA), oleoylethanolamide (OEA), and palmitoylethanolamide (PEA), on microglial chemotactic activity and found that the combination of these three endovanilloids was necessary to induce microglial chemotaxis (relative chemotactic ratio vs. control, 1.378 ± 0.125, \( p > 0.05 \) in AEA (30 \( \mu \)M); 0.848 ± 0.079, \( p > 0.05 \) in AEA (30 \( \mu \)M) + OEA (1 \( \mu \)M); 0.961 ± 0.037, \( p > 0.05 \) in AEA (30 \( \mu \)M) + PEA (1 \( \mu \)M); and 1.967 ± 0.482, \( p < 0.05 \) in AEA (30 \( \mu \)M) + OEA (1 \( \mu \)M) + PEA (1 \( \mu \)M), \( n = 4 \)). Furthermore, the chemotaxis induced by the mixture of the three endovanilloids was inhibited by EUK-134 (3 \( \mu \)M) (Fig. 6A) but was not observed in microglia derived from TRPV1-KO mice (Fig. 6B). To determine whether the mixture of these three endovanilloids induced mitochondrial depolarization, we evaluated the m\( \Delta \psi \) in microglia using JC-1 dye. The mixture of the three endovanilloids induced
mitochondrial depolarization in microglia derived from WT mice, and this depolarization was blocked by SB366791 (3 µM) (Fig. 6C). There was no effect in microglia derived from TRPV1-KO mice (Fig. 6D). These data suggest that the mixture of these three endovanilloids induces microglial chemotaxis via TRPV1 activation, mitochondrial depolarization, and mtROS production.

**Discussion**

In this study, we demonstrated that TRPV1 is functionally expressed in mitochondria and its activation triggers an increase in intramitochondrial Ca\(^{2+}\) concentration, depolarization of mitochondria, resultant mtROS production and enhancement of chemotactic activity in microglia.

Endovanilloids are one group of endogenous TRPV1 agonists (Zygmunt et al., 1999), and activation of postsynaptic TRPV1 by AEA plays a pivotal role in the induction of long-term depression in hippocampal dentate gyrus granular cells (Chávez et al., 2010) and in dopamine D2 receptor-expressing medium spiny neurons of the nucleus accumbens (Grueter et al., 2010) under physiological conditions. Moreover, endovanilloids are not only released into the synaptic cleft but also spill over from synapses and bind cannabinoid receptors in astrocytes that modulate neighboring synapses by releasing glutamate (Navarrete et al., 2010). The role of endovanilloids under pathological conditions is also important. Recently, neuronal precursor cells were reported to migrate to high-grade astrocytomas, reduce glioma expansion and prolong survival time by releasing certain endovanilloids that open glioma TRPV1 channels in the ER and induce glioma cell death (Stock et al., 2012). In that study, they examined three endovanilloids (AEA, OEA, and PEA) and found that not one or two but all three endovanilloids were necessary to cause TRPV1-mediated glioma cell death, consistent with our result that the combination of three endovanilloids was needed to induce microglial migration. Glioma tissue consists of tumor cells and up to 30% microglia or macrophages, and the microglia are attracted to the glioma site and accumulate at its margins, in particular (Hanisch et al., 2007). In several pathological conditions, the concentrations of endovanilloids in the CNS are increased in several area of the brain. For instance, Panikashvili et al. (2001) demonstrate that the level of 2-arachidonoyl glycerol, which behaves also as an endogenous agonist of TRPV1 (Zygmunt et al., 2013), is significantly elevated after closed head injury (CHI) in mice. Marsicano et al. (2003) show that the amount of hippocampal AEA is significantly increased after kainic acid injection-induced excessive seizures. Furthermore, PEA and AEA are greatly increased in mouse cerebral cortex after focal ischemia and PEA potentiates AEA-induced microglial migration, without affecting other parameters of microglial activation, such as proliferation, particle engulfment, and NO production (Franklin et al., 2003). What is particularly interesting in that report with regard to the present study is that the receptors engaged by PEA are pharmacologically distinct from CB1 and CB2 cannabinoid receptors. This implies that TRPV1 may contribute to this phenomenon because in our study capsaicin did not affect the NO production induced by LPS/IFN\(_\gamma\) but induced migration. Thus, TRPV1-mediated microglial chemotaxis may have an
important role in microglial accumulation via a mechanism involving endovanilloids.

TRPV1 can also be activated or modified by intracellular signaling following the activation of other receptors. For example, PKCε is bound to the inner mitochondrial membrane and phosphorylates the mitochondrial K_{ATP} channel to modulate its activity (Costa et al., 2008), indicating that PKCε is functionally located on the inner mitochondrial membrane. In addition, hypoxia, one of the main complications in diabetes, induces translocation of PKCε to the plasma membrane, and PKCε phosphorylates the serine residues of TRPV1 (Numazaki et al., 2002), which results in the potentiation of TRPV1 and the genesis of early diabetic neuropathy (Ristoiu et al., 2011). Moreover, activation of PLC downstream of bradykinin or TrkA receptors by their agonists may potentiate TRPV1 through direct activation of lipid metabolites, such as arachidonic acid and the hydroperoxyeicosatetraenoic acid generated by phospholipase A2 and lipoxygenase (Hwang et al., 2000). Although the present study suggests that direct activation of TRPV1 augmented chemotactic activity in microglia, we cannot exclude the possibility that microglia sense other signals through their receptors and migrate to the injury site via PKCε and PLC activation followed by TRPV1 activation because microglia express functional metabotropic receptors, such as mGluRs (Byrnes et al., 2009) and P2Y receptors (Koizumi et al., 2013).

In the present study, capsaicin induced an increase in the intracellular mitochondrial Ca^{2+} concentration and mitochondrial depolarization, whereas capsaicin induced no responses in the electrophysiological and intracellular Ca^{2+} imaging experiments in microglia. Mitochondria are capable of taking up Ca^{2+} ions from the cytosol (Deluca et al., 1961; Vasington et al., 1962). Although the intramitochondrial Ca^{2+} concentration is higher than the intracellular Ca^{2+} concentration, the mΔΨ is sufficient to induce Ca^{2+} uptake rather than Ca^{2+} release (Rizzuto et al., 2012). In our study, microglia derived from TRPV1-KO mice showed a prolonged t_{1/2} of the Ca^{2+} response induced by 10 µM ATP compared with microglia derived from WT mice. Thus, TRPV1 appears to be located neither on the plasma membrane nor on the intracellular membranes of the compartment of the Ca^{2+} store, but is likely located in mitochondria.

It is known that mtROS plays a pivotal role in regulating cellular functions. For instance, in cultured human umbilical vein endothelial cells, VEGF promotes mtROS production and induces cell migration through Rac1 activation (Wang et al., 2011). In murine peritoneal macrophages, lysophosphatidylcholine, released from apoptotic cells, enhances mtROS production and triggers chemotactic activity through AMPK activation (Jiang et al., 2013). These results imply that mitochondria in microglia may also regulate chemotactic activity, in addition to regulating production of pro-inflammatory mediators, which is triggered by the activation of nuclear factor kappa-light-chain-enhancer of activated B cells and MAPK signaling following mtROS production induced by increased mitochondrial fission in LPS-stimulated microglia (Park et al., 2013). Furthermore, different mtROS levels regulate different cellular functions. Whereas high levels of mtROS induce apoptosis and autophagy, low levels of mtROS participate in the process of hypoxia adaptation, and moderate levels of mtROS are involved in regulating the
production of pro-inflammatory cytokines by directly activating the inflammasome and MAPK (Li et al., 2013). Because 10 µM capsaicin did not induce cell death in microglia in the present study (Supplementary figure 1), and the expression level of TRPV1 is not changed between peritoneal cells obtained from sham and cecal ligation and puncture model mice (Fernandes et al., 2012), our data indicated that mitochondrial depolarization induced by TRPV1 activation produced low or moderate levels of mtROS, which regulated MAPK activity followed by augmentation of microglial chemotaxis and mitochondrial TRPV1 activation may be independent of other microglial functions.

Although previous research has shown that ROS play an important role in cell migration, little is known about the mechanisms underlying ROS-induced augmentation of microglial migration. Recent studies show that H₂O₂ has a pivotal role of immediate wound attractant signaling in macrophages of Drosophila embryo (Moreira et al., 2010) and leukocytes of zebrafish in vivo (Niethammer et al., 2009). It has been demonstrated that H₂O₂ itself induces chemotactic activity in mouse neutrophils (Klyubin et al., 1996) and in a keratinocyte cell line in vitro (Loo et al., 2011), indicating that extracellular ROS can play an important role in chemotactant signaling. What then is the role of intracellular ROS in cell migration? ROS can influence F-actin dynamics both directly and indirectly. Migrating cells produce ROS at the membrane ruffles, which directly increases actin polymerization (Ikeda et al., 2005). The indirect regulation of actin dynamics by ROS occurs via activation of redox-sensitive enzymes. For instance, ROS oxidizes tyrosine phosphatase, which induces the decrease in RhoA activity required for Rac-induced formation of membrane ruffles (Nimnual et al., 2003). ROS directly activates Gαi and Gαo and stimulates the PI3K, Akt, and ERK cascades, which are related to actin organization (Nishida et al., 2000). ROS modulate MAPK signaling (Liu et al., 2009; Bhatt et al., 2002; Ogura et al., 1998; Aikawa et al., 1997; Guyton et al., 1996), and MAPK phosphatase-1 is a central redox-sensitive regulator of monocyte adhesion and chemotaxis (Kim et al., 2012). Thus, the generation of ROS is an important signaling mechanism regulating cell migration.

In conclusion, this study indicates that microglial TRPV1 is located in mitochondria, and the activation of this channel evokes mitochondrial depolarization followed by mtROS production, which induces the activation of cell migration via MAPK activation. Microglial TRPV1 may play an important role in enhancing microglia accumulation at sites with abundant endovanilloids.

**Figure legends**

Figure 1.
TRPV1 activation enhances chemotactic activity in cultured murine microglia. A–B, Chemotactic activity of microglia from wild-type (A) or TRPV1-KO (B) mice induced by capsaicin (1–10 µM) with or without SB366791 (3 µM) or BAPTA-AM (10 µM) was quantitated with the chemotactic assay as described in the Materials and Methods. Data are presented as means with SEM. **p < 0.01; ***p < 0.001 vs. non-treated; ##p < 0.01; ###p < 0.001 vs. 10 µM capsaicin treated; n = 4–8. C, Microglial cultures were scratched as described in the Materials and Methods, and phase contrast images were acquired with low magnification at 0 h (left) and after 24 h (right) with or without capsaicin (10 µM). Dotted lines represent the initial position of the microglia. Note that the number of the microglia invading the wound is increased. D–E, Microglia from wild-type (D) or TRPV1-KO (E) mice were plated on coverslips and treated with or without capsaicin (CAP, 10 µM) and/or the TRPV1 selective blocker SB366791 (SB, 3 µM). After 24 h, cells were fixed and stained with DAPI and Alexa Fluor 488-conjugated phalloidin to visualize nuclei and actin filaments. White arrows indicate membrane ruffles, signifying migrating cells. Scale bar: 30 µm.

Figure 2.
TRPV1 activation is not involved in additional microglial functions. A–B, ATP (100 µM)-induced chemotactic activity of wild-type (A) or TRPV1-KO (B) microglia was quantified with the chemotactic assay as described in the Materials and Methods. ***p < 0.001 vs. control (Cont.); n = 4. C–H, Microglial cultures were treated with or without capsaicin (10 µM) in addition to LPS (100 ng/mL) and IFNγ (10 ng/mL) (LPS/IFNγ) for 48 h. The concentration of NO in the media of wild-type (C) or TRPV1-KO (D) cultures was determined using the Griess reaction. The concentrations of TNF-α (E, F) and IL-6 (G, H) in the supernatants of wild-type (E, G) or TRPV1-KO (F, H) cultures were determined with an ELISA. Data are
Figure 3.
TRPV1 is expressed intracellularly in microglia. A, HEK293T cells stably expressing rTRPV1 (upper) or microglia derived from wild-type (middle) or TRPV1-KO (lower) mice were plated on coverslips, fixed, and immunostained with TRPV1 antibody. Scale bar: 10 µm. B, same as A, but cells were stained with DAPI in addition to anti-TRPV1 antibody and examined at low-magnification. Scale bar: 50 µm. C, Microglia were plated on coverslips, fixed, and immunostained or stained with TRPV1 antibody (green) and organelle markers (ER, calregulin; lysosome, Lamp1; Golgi, 58K Golgi protein; mitochondria, MitoTracker Red) (red). Magnified pictures are higher magnification of the boxed areas in merged pictures. Scale bar: 10 µm (Merge) or 1 µm (Magnified).

Figure 4.
Functional TRPV1 is located on mitochondria in microglia. A–C, HEK293T cells transiently expressing rTRPV1 (A) or wild-type microglia (B–C) were plated on coverslips and whole-cell recording (A–B, left, time course; right, current-voltage relationship) or Fura-2 intracellular Ca²⁺ imaging (C, n = 100 cells) was performed, where Ca²⁺ ionophore ionomycin at 3 µM was used to elicit maximum Ca²⁺ responses. D–E, Microglia derived from wild-type or TRPV1-KO mice were plated on glass-bottom dishes and Rhod-5N intramitochondrial Ca²⁺ imaging was performed. Representative averaged curves with error bars (SEM) are shown in D (wild-type, n = 104 ROI; TRPV1-KO, n = 98 ROI), and E represents statistical analysis of mitochondrial Ca²⁺ influx induced by capsaicin (10 µM). *p < 0.05 vs. wild-type; n = 3–4. F–H, Microglia derived from wild-type or TRPV1-KO mice were plated on coverslips, and Fura-2 intracellular Ca²⁺ imaging was performed in the presence or absence of SB366791 (3 µM). Representative averaged curves with error bars (SEM) are shown in F (wild-type, n = 85 cells; wild-type + SB366791, n = 82 cells; TRPV1-KO, n = 92 cells), and G–H represent statistical analyses of amplitudes (G) and times to half-amplitude (H) of the 10 µM ATP-evoked responses. *p < 0.05 vs. wild-type; n = 7–9. I–J, Microglia derived from wild-type (I) or TRPV1-KO (J) mice were plated on glass-bottom dishes and treated with or without capsaicin (10 µM) and/or SB366791 (3 µM). After 24 h, changes in the mitochondrial membrane potential were detected using the JC-1 assay as described in the Materials and Methods. **p < 0.01 vs. control (Cont.); n = 4–5. Data are presented as means with SEM.

Figure 5.
Capsaicin-induced chemotaxis is mediated by mitochondrial ROS, p38 MAPK, and JNK. A, Chemotactic activity of wild-type microglia in the presence of rotenone (0.3 µM) was quantitated with the chemotactic assay as described in the Materials and Methods. Note that ATP (100 µM) significantly induced chemotaxis even in the presence of rotenone. n.s., not significant; **p < 0.01; n = 4–8. B, The effect of antioxidants (see Results for details) on the 10 µM capsaicin-induced chemotactic
activity of wild-type microglia was quantitated with the chemotactic assay. ***p < 0.001 vs. control (Cont.): #p < 0.05; ###p < 0.001 vs. 10 µM capsaicin treated; n = 4.

C–D, Chemotactic activity of microglia derived from wild-type (C) or TRPV1-KO (D) mice induced by H₂O₂ (10 µM) with or without SB366791 (3 µM), EUK-134 (3 µM), PD98059 (10 µM), SB203580 (30 µM), or SP600125 (30 µM) was quantitated with the chemotactic assay. *p < 0.05; ***p < 0.001 vs. Cont.; ##p < 0.01, ###p < 0.001 vs. 10 µM H₂O₂ treated; n = 4–16.

E, Chemotactic activity of wild-type microglia induced by capsaicin (10 µM) in the presence of PD98059 (10 µM), SB203580 (30 µM), or SP600125 (30 µM) was quantitated with the chemotactic assay. *p < 0.05 vs. Cont.; ##p < 0.01 vs. 10 µM capsaicin treated; n = 4.

All data are presented as means with SEM.

Figure 6.
Endovanilloids enhance chemotactic activity via TRPV1 activation in microglia. A–B, Chemotactic activity of microglia derived from wild-type (A) or TRPV1-KO (B) mice induced by a mixture of endovanilloids (AEA [30 µM] + OEA [1 µM] + PEA [1 µM]) with or without EUK-134 (3 µM) was quantitated with the chemotactic assay. **p < 0.01 vs. control (Cont.): #p < 0.05 vs. treatment with the mixture of endovanilloids; n = 4. C–D, Wild-type (C) or TRPV1-KO (D) microglia were plated on glass-bottom dishes and treated with or without the mixture of endovanilloids (same as A–B) with or without SB366791 (3 µM). After 24 h, changes in the mitochondrial membrane potential were detected using the JC-1 assay as described in the Materials and Methods. *p < 0.05 vs. Cont.; ##p < 0.01 vs. treatment with the mixture of endovanilloids; n = 4–5.
