1 **Abstract**

2 The influence of water-miscible alcohols (methanol, 1-propanol, 2-propanol and  
3 *t*-butyl alcohol) on the isomerization of glucose to fructose and mannose was  
4 investigated under subcritical aqueous conditions (180–200 °C). Primary and secondary  
5 alcohols promoted the conversion and isomerization of glucose to afford fructose and  
6 mannose with high and low selectivity, respectively. On the other hand, the  
7 decomposition (side-reaction) of glucose was suppressed in the presence of the primary  
8 and secondary alcohols compared with that in subcritical water. The yield of fructose  
9 increased with increasing concentration of the primary and secondary alcohols, and the  
10 species of the primary and secondary alcohols tested had little effect on the  
11 isomerization behavior of glucose. In contrast, the isomerization of glucose was  
12 suppressed in subcritical aqueous *t*-butyl alcohol. Both the conversion of glucose and  
13 the yield of fructose decreased with increasing concentration of *t*-butyl alcohol. In  
14 addition, mannose was not detected in reactions using subcritical aqueous *t*-butyl  
15 alcohol.

16

17 **Keywords:** fructose; glucose; isomerization; mannose; subcritical aqueous ethanol

18 **Introduction**

19 In recent decades, subcritical water has been widely employed as a reaction medium  
20 and extractant<sup>1-4)</sup> due to its high ion product and low dielectric constant. With these two  
21 properties, subcritical water can work as a specific solvent, influencing chemical  
22 reactivity,<sup>5)</sup> and also as an environmentally friendly acid-base catalyst for hydrolysis and  
23 isomerization reactions.<sup>6-9)</sup> Many researchers have focused on the decomposition,  
24 hydrolysis and isomerization behavior of saccharides in subcritical water.<sup>10-16)</sup> It has  
25 also been reported that glucose-, mannose-, and fructose-type monosaccharides can  
26 mutually isomerize through an alkali-catalysis-like pathway in subcritical water.<sup>17,18)</sup>  
27 When isomerization of glucose, mannose, and fructose was performed in subcritical  
28 water, mannose could isomerize to fructose more easily than could other hexoses.<sup>17)</sup>  
29 However, the yields of fructose from both mannose and glucose were not high.

30 The influence of the addition of alcohols on the decomposition of disaccharides and  
31 the isomerization of monosaccharides has been investigated.<sup>19-21)</sup> It was reported that  
32 ethanol can markedly accelerate the alkaline metal hydroxide- and disodium  
33 pentasilicate-catalyzed isomerization of glucose to fructose, and *vice versa*, and can  
34 change the apparent isomerization equilibrium.<sup>20,21)</sup> In the case of the calcium  
35 chloride-catalyzed isomerization of glucose in basic solutions, the reaction reached

36 equilibrium faster in aqueous methanol than in aqueous ethanol.<sup>22)</sup> Fructose and  
37 mannose were obtained with almost the same selectivity in aqueous methanol, while  
38 mannose was produced with a higher selectivity than fructose in aqueous ethanol at  
39 65 °C for 10 min.<sup>22)</sup> However, unlike methanol and ethanol, 1- and 2-propanol cannot  
40 give these satisfactory results in alkali-catalyzed isomerization of monosaccharides.<sup>22)</sup>

41 Our preliminary work showed that subcritical aqueous ethanol could remarkably  
42 promote the isomerization of glucose and mannose to fructose and that the  
43 isomerizations were accelerated with increasing ethanol concentration.<sup>23)</sup> Therefore, in  
44 this study, we investigated the influence of mixtures of water and water-miscible alcohol  
45 (methanol, ethanol, 1-propanol, 2-propanol, and *t*-butyl alcohol) on the isomerization of  
46 glucose under subcritical conditions.

47

## 48 **Materials and Methods**

49 *Materials.* Straight-chain alcohols (methanol, ethanol, and 1-propanol), branched-chain  
50 alcohol (2-propanol and *t*-butyl alcohol), D-glucose (>99%), and D-fructose (>99%)  
51 were purchased from Wako Pure Chemical Industries (Osaka, Japan). D-Mannose  
52 (>99%) was purchased from Nacalai Tesque (Kyoto, Japan).

53

54 *Isomerization of glucose in subcritical aqueous alcohols.* Glucose was dissolved in  
55 distilled water and then mixed with alcohol to produce glucose solution at a final  
56 concentration of 0.5% (w/v) and an alcohol concentration of 0–80% (v/v). The solution  
57 was sonically degassed under reduced pressure before subcritical treatment. The  
58 solution reservoir was connected to a helium gasbag to prevent redissolution of  
59 atmospheric oxygen. The solution was delivered into a coiled stainless steel tubular  
60 reactor (0.8 mm $\phi$   $\times$  1.0 m for subcritical aqueous methanol, ethanol, and 1- and  
61 2-propanol and 0.8 mm $\phi$   $\times$  2.0 m for subcritical aqueous *t*-butyl alcohol) immersed in  
62 an SRX-310 silicone oil bath (Dow Corning Toray Silicone Co., Ltd., Tokyo, Japan) by  
63 using an LC-10AD VP HPLC pump (Shimadzu Corp., Kyoto, Japan). In order to  
64 rapidly terminate the reaction, the reactor effluent was directly introduced into a  
65 stainless-steel tube (0.8 mm $\phi$ ) that was immersed in an ice bath. The temperature and  
66 residence time were set to 180 °C and 30–500 s for isomerization in aqueous methanol,  
67 ethanol, and 1- and 2-propanol. For isomerization in subcritical aqueous *t*-butyl alcohol,  
68 they were set to 180 °C or 200 °C and 100–1000 s. The pressure inside the reactor was  
69 regulated at *ca.* 10 MPa using a back pressure regulator (Upchurch Scientific, Oak  
70 Harbor, Washington, USA).

71 The residence time was calculated according to our previous method.<sup>24)</sup> The density

72 of methanol, or 1- or 2-propanol under subcritical conditions was calculated based on  
73 the reported data.<sup>25-27)</sup> However, because the density of *t*-butyl alcohol under subcritical  
74 conditions was not reported, it was assumed to be the same as that of 2-propanol.

75 The number of replication is one because the error was small for the isomerization  
76 of glucose in 40% (v/v) subcritical aqueous ethanol in triplicate<sup>23)</sup>.

77

78 *Carbohydrate analysis.* The reactor effluent was collected in a test tube for HPLC  
79 analysis. The HPLC system consisted of an LC-10AD VP HPLC pump (Shimadzu  
80 Corp.), an RI-101 refractometer (Showa Denko K. K., Tokyo), and a Cosmosil Sugar-D  
81 column (4.6 mm $\phi$   $\times$  250 mm, Nacalai Tesque). A mixture of water and acetonitrile  
82 (20:80, v/v) was employed as the mobile phase at a flow rate of 1 mL/min. The column  
83 was maintained at 30 °C in a CTO-10A VP column oven (Shimadzu Corp.).

84

## 85 **Results and Discussion**

### 86 *Isomerization of glucose in subcritical aqueous alcohols*

87 Figure 1 shows the typical change in the fraction of remaining glucose with residence  
88 time at 180 °C in subcritical water and in 60% (v/v) subcritical aqueous alcohols. When  
89 glucose was treated for 500 s in subcritical water, the conversion was about 13%.

90 However, the conversion of glucose at a residence time of 500 s was almost doubled  
91 and was 27–31% in the presence of any of the water-miscible primary or secondary  
92 alcohols. Our preliminary work showed that ethanol can promote the conversion of  
93 glucose.<sup>23)</sup> These facts show that addition of the primary and secondary alcohols will  
94 also achieve this conversion. In addition, there was no obvious difference in the  
95 promotion ability among the four alcohols.

96 As in subcritical aqueous ethanol,<sup>23)</sup> fructose were produced from glucose with high  
97 yield and selectivity, while mannose was produced with low yield and selectivity in  
98 subcritical aqueous methanol, and 1- and 2-propanol (Fig. 2), where the selectivity was  
99 defined as the molar ratio of the product to the consumed substrate. The yields of both  
100 fructose and mannose were increased by the addition of these alcohols. These facts  
101 indicate that the primary and secondary alcohols used can also promote isomerization.  
102 The type of alcohol slightly affected the yields of fructose and mannose. This is in  
103 contrast to the reported results, which showed that methanol promoted isomerization  
104 more efficiently than ethanol in the alkali-catalyzed isomerization of glucose at low  
105 temperature, and that 1- and 2-propanol could not promote the isomerization  
106 reaction.<sup>20,22)</sup> On the other hand, the addition of *t*-butyl alcohol suppressed the  
107 conversion of glucose as discussed in detail later.

108 *Effect of the concentration of methanol, and 1- and 2-propanol on the isomerization*  
109 *of glucose*

110 Figure 3 shows the typical influence of the concentrations of methanol, and 1- and  
111 2-propanol, on the selectivities of the derived fructose and mannose, yield of fructose,  
112 and fraction of degraded hexoses, for the treatment of glucose at 180°C for 500 s. The  
113 yields of fructose increased with increasing concentration of the alcohols. In the 0–40%  
114 (v/v) concentration range, the yield of fructose showed a weak dependence on the  
115 concentration of the alcohols. However, in the higher concentration range, increasing  
116 the concentration of the alcohols, especially of 2-propanol, greatly raised the yield of  
117 fructose. Dependence of the selectivity for fructose on the alcohol concentration was  
118 different to that of the yield: the selectivity for fructose reached a maximum value in  
119 60% (v/v) alcohol and then decreased when the concentration of the alcohols increased  
120 to 80% (v/v). One reason for this decrease in 80% (v/v) alcohol may be that the  
121 decomposition of fructose is promoted by the addition of alcohols.<sup>23)</sup> Although the  
122 addition of alcohol can also promote the decomposition of hexoses,<sup>23)</sup> the fraction of  
123 degraded hexoses did not increase with an increasing concentration of methanol,  
124 1-propanol, or, especially, 2-propanol. When the concentration of 2-propanol was  
125 increased to 80% (v/v), most of the consumed glucose was isomerized to fructose and

126 mannose, and 2-propanol exhibited a better effect than methanol and 1-propanol on the  
127 isomerization of glucose to fructose. On the other hand, selectivity for mannose was  
128 kept at a low level in the presence of the three alcohols.

129 The mechanism of the promotion of isomerization in subcritical aqueous alcohols is  
130 unclear. However, isomerization of glucose depended very little on the particular  
131 primary and secondary alcohols in subcritical aqueous conditions. Similarity in the  
132 behaviors of methanol, ethanol, and 1- and 2-propanol in promoting isomerization  
133 would indicate that these alcohols promote the isomerization by the same mechanism.  
134 Glucose, mannose, and fructose can be mutually interconverted by acid, base, or  
135 acid-base catalysts.<sup>28-32)</sup> Recent research demonstrated that, in aqueous alcohol with  
136 high alcohol concentration, the strength of the bond between the proton and oxygen  
137 atom of the alcoholic hydroxyl group was weaker than in pure alcohol, especially when  
138 the temperature exceeded 130 °C.<sup>33)</sup> It was also found that glucose could exchange its  
139 C-1 proton with the proton of the hydroxyl group of methanol to form fructose.<sup>34)</sup>  
140 Accordingly, a possible mechanism under the subcritical aqueous conditions is that  
141 there is a higher dissociation of the alcohol (RO-H) to RO<sup>-</sup> and H<sup>+</sup>, either of which can  
142 catalyze the isomerization. Because the proton-accepting or electron-donating ability of  
143 RO<sup>-</sup> is higher than that of OH<sup>-</sup>,<sup>35)</sup> RO<sup>-</sup> could promote the isomerizations more

144 effectively than  $\text{OH}^-$  through alkali isomerization.

145

146 *Isomerization of glucose in subcritical aqueous t-butyl alcohol*

147 The concentration of *t*-butyl alcohol also affected the conversion of glucose (Fig. 4).

148 However, in contrast to the cases for methanol, ethanol, and 1- and 2-propanol, the

149 isomerization behavior was different in *t*-butyl alcohol: glucose was converted more

150 slowly with an increasing concentration of *t*-butyl alcohol compared to the conversion

151 of glucose in subcritical water. When glucose was treated in 20% (v/v) *t*-butyl alcohol at

152 180 °C for 1000 s, its conversion was almost the same as that at 180 °C for 400 s in

153 subcritical water.

154 Fructose was also formed from glucose in subcritical aqueous *t*-butyl alcohol (Fig. 5).

155 However, the isomerization behavior was different from that in other subcritical

156 aqueous alcohols, as described above: only fructose was detected, and mannose was not

157 formed in the presence of *t*-butyl alcohol. Besides, the yield of fructose was much lower

158 than those obtained in subcritical water and in the presence of the other alcohols tested

159 under the same reaction conditions.

160 The formation of fructose was slower at a higher *t*-butyl alcohol concentration.

161 However, the conversion and isomerization were accelerated by increasing the

162 temperature (Figs. 4 and 5). When glucose was treated at 200 °C for 1000 s in 60%  
163 (v/v) *t*-butyl alcohol, the conversion of glucose and the yield of fructose reached about  
164 25% and 10%, respectively, which was about 3- and 2.5-fold higher, respectively, than  
165 those obtained at 180 °C.

166 Figure 6 shows the typical influence of *t*-butyl alcohol concentration on the  
167 selectivity for fructose, the yield of fructose, and the fraction of degraded hexoses, for  
168 the treatment of glucose at 180 °C for 1000 s. The dependence of the selectivity for  
169 fructose on the *t*-butyl alcohol concentration was different to that of the other alcohols  
170 tested. The selectivity for fructose decreased with increasing *t*-butyl alcohol  
171 concentration. In particular, there was a large decrease in the selectivity when the  
172 concentration of *t*-butyl alcohol exceeded 40% (v/v). The yield of fructose almost  
173 linearly decreased with increasing *t*-butyl alcohol concentration. The fraction of  
174 degraded hexoses was also low in subcritical aqueous *t*-butyl alcohol and was only  
175 slightly affected by the *t*-butyl alcohol concentration.

176 In line with the proposed mechanism regarding the promotion of the isomerization of  
177 glucose by primary and secondary alcohols, the reason for the suppression of the  
178 isomerization of glucose in subcritical aqueous *t*-butyl alcohol may be that *t*-butyl  
179 alcohol would be dissociated to H<sup>+</sup> and the *t*-butoxy anion, (CH<sub>3</sub>)<sub>3</sub>CO<sup>-</sup>, which possesses

180 much stronger proton-accepting ability than the alkoxide anions of the other alcohols  
181 tested. However, the bulky *t*-butyl group gives the *t*-butoxy anion greater steric  
182 hindrance, which could suppress the isomerization. As a result, the addition of *t*-butyl  
183 alcohol only caused a diluting effect on the water concentration, which was similar to  
184 the addition of ethanol to subcritical water during the hydrolysis of sucrose.<sup>24)</sup>

185 In conclusion, the isomerization of glucose was promoted with increasing alcohol  
186 concentration in subcritical aqueous primary and secondary alcohols. The type of  
187 alcohol slightly affected the isomerization. However, the addition of *t*-butyl alcohol  
188 suppressed the isomerization. These facts suggest a mechanism for the promotion of the  
189 monosaccharide isomerization in subcritical aqueous alcohols.

297

298 **Fig. 3.** Effects of the alcohol concentration on the selectivities of ( $\diamond$ ) fructose and ( $\square$ )  
299 mannose, ( $\triangle$ ) fraction of disappeared hexoses, and ( $\circ$ ) yield of fructose for the  
300 treatment of glucose at 180 °C for 500 s. (a) Methanol, (b) 1-propanol, (c) 2-propanol.

301

302 **Fig. 4.** Changes in the fraction of remaining glucose with residence time at 180 °C in  
303 ( $\diamond$ ) 80%, ( $\square$ ) 60%, ( $\triangle$ ) 40%, ( $\circ$ ) 20%, and ( $\triangleright$ ) 0% (v/v) *t*-butyl alcohol and at ( $\blacksquare$ )  
304 200 °C in 60% (v/v) *t*-butyl alcohol.

305

306 **Fig. 5.** Yields of fructose derived from glucose at different residence times in subcritical  
307 aqueous *t*-butyl alcohol. The symbols are the same as those in Fig. 4.

308

309 **Fig. 6.** Effects of *t*-butyl alcohol concentrations on ( $\diamond$ ) the selectivity of fructose, ( $\Delta$ )  
310 the fraction of degraded hexoses, and ( $\circ$ ) the yield of fructose for the treatment of  
311 glucose at 180 °C for 1000 s.
