Stability Analysis of Space-Time Finite Integration Schemes

Tetsuji Matsuo, Jun Kawahara, Tomohiro Shimoi and Takeshi Mifune
Graduate School of Engineering, Kyoto University, Nishikyo-ku, Kyoto 615-8510, Japan

Abstract—The numerical stability of a space-time finite integration (FI) method is examined. The growth rate of instability is evaluated by a numerical eigenvalue analysis formulated from the explicit time-marching scheme of the FI method. The space-time subgrid schemes using the 3D and 4D space-time FI methods are shown to be conditionally stable. For the constitutive relation at the subgrid connections, a symmetric correction is proposed that does not induce numerical instability. The staircase-type space-time subgrid improves stability compared with the straight-type subgrid.

Index Terms—eigenvalue analysis, space-time grid, subgrid, symmetric correction.

I. INTRODUCTION

The finite integration (FI) method (Weiland 1996) (Lager et al. 2003) (Codecasa and Politi 2008) has been reassessed for time-domain computations on unstructured spatial grids of electromagnetic fields. Similar to the FDTD method, the FI method uses a uniform time-step, which is restricted by the Courant-Friedrichs-Lewy (CFL) condition (Taflove and Hagness 2006) based on the smallest spatial grid size.

Previous work (Matsuo 2011) (Kawahara et al. 2013) introduced a space-time FI method to relax the CFL condition that achieves non-uniform time-steps on 3D and 4D space-time grids. A numerical eigenvalue analysis (Matsuo and Mifune 2014) showed that 3D space-time FI scheme having a temporal grid subdivision can be stable. However, the eigenvalue analysis for the space-time FI scheme including both temporal and spatial grid subdivision has not yet been performed.

This study evaluates the numerical stability of 3D and 4D simple subgrid scheme (Matsuo et al. 2015) using the space-time FI method.

II. SPACE-TIME FINITE INTEGRATION METHOD

A. Electromagnetic Equations in Space-Time

The coordinate system is denoted by (ct, x, y, z) = (x^0, x^1, x^2, x^3), where c = 1/\sqrt{\varepsilon_0\mu_0} and \varepsilon_0 and \mu_0 are respectively the permittivity and permeability of the vacuum. The Maxwell equations, given in the integral form, are:

\[
\begin{align*}
\oint_{\partial \Omega} F &= 0, \quad \oint_{\partial \Omega} E &= \oint_{\partial \Omega} J \\
F &= -\sum_{j=1}^{3} E_j dx^j \cdot dx^i + \sum_{j=1}^{3} c_B dx^j \cdot dx^i \\
E &= \sum_{j=1}^{3} B_j dx^j \cdot dx^i + \sum_{j=1}^{3} c_D dx^j \cdot dx^i \\
J &= c \rho dx^1 \cdot dx^i + \sum_{j=1}^{3} J dx^j \cdot dx^i.
\end{align*}
\]  (1)

where (i, j, k) is a cyclic permutation of (1, 2, 3); \Omega and \Omega are hypersurfaces in space-time; \rho is the electric charge density. In the FI method, the electromagnetic variables are defined as:

\[
\begin{align*}
f &= \oint_{\partial \Omega} F, \quad g &= \oint_{\partial \Omega} E
\end{align*}
\]  (2)

B. Explicit Time-Marching Scheme

The FI method is generally formulated with the Maxwell grid equations using the incidence matrices from graph theory. Following (Kawahara et al. 2013), the geometrical formulation of (x^0, x^1, x^2)-3D space-time FI method is summarized in Appendix A, where the propagation of (E_1, E_2, B_3) is described. Equation (27) or (29) in Appendix gives an implicit expression for the time-evolution of the electromagnetic wave. There exist space-time grids having explicit time-marching schemes that are compatible with (27) or (29). Their numerical stability is discussed in the following sections.

III. STABILITY ANALYSIS

Figure 1 shows an example of a space-time grid having a temporal period \Delta \phi = \Delta \omega, where the solid and dashed lines are the primal and dual grids, respectively. The variables given by (3) are periodically allocated along the x^i-direction on the space-time grid. The variables are accordingly denoted \mathbf{V}^0, \mathbf{V}^1, \ldots, where \mathbf{V}^{n+1} is assigned after \mathbf{V}^n by the time-interval \Delta \omega, as illustrated in Fig. 2. The variable vector \mathbf{V}^n is divided into \mathbf{v}^n and \mathbf{u}^n where the components of \mathbf{v}^n are linearly independent and the components of \mathbf{u}^n are given as linear combinations of the components of \mathbf{v}^n, i.e., \mathbf{u}^n = \mathbf{P} \mathbf{v}^n with \mathbf{P} a constant matrix. The numerical stability of the time-marching scheme is evaluated using the eigenvalues of matrix \partial \mathbf{v}^{n+1}/\partial \mathbf{v}^n.
If the explicit time-marching scheme exists, its derivation from (27) takes the form

\[ A_n v^{n+1} + B_n u^n + A_{n+1} v^{n+1} + B_{n+1} u^{n+1} = (A_0 + B_0 P) v^n + A_1 v^{n+1} + B_1 u^{n+1} = 0 \]  

where \( A_i \) and \( B_i \) \((i = 1, 2)\) are \( N \times N \) and \( M \times M \) constant matrices, respectively; \( N \) and \( M \) are the dimensions of \( v \) and \( u \). The influence of permittivity/permeability of material is included in \( A_i \) and \( B_i \).

From (6), \( \partial v^{n+1}/\partial v^n \) is obtained by solving

\[ \begin{pmatrix} A_i & B_i \end{pmatrix} \begin{pmatrix} \partial v^{n+1} \\ \partial u^n \end{pmatrix} = -(A_0 + B_0 P) \left( \begin{array}{c} u^n \\ v^n \end{array} \right) \]  

(7)

If \( u^{n+1} \) and \( v^{n+1} \) are determined from the pairs \( v^n \) and \( u^n \) and \( v^n \) and \( u^{n+1} \), respectively, the time-marching scheme is rewritten as:

\[ u^{n+1} = Q u^n + R v^n, \quad v^{n+1} = S v^n + T u^{n+1} \]  

(8)

where \( Q, R, S, \) and \( T \) are constant matrices. Equation (8) gives

\[ \partial v^{n+1}/\partial v^n = S + T (R + QP) \]  

(9)

By setting

\[ A_i = \begin{pmatrix} S \\ R \end{pmatrix}, \quad B_i = \begin{pmatrix} O \\ O \end{pmatrix}, \quad A_i = \begin{pmatrix} -I_N \\ O \end{pmatrix}, \quad B_i = \begin{pmatrix} T \\ -I_M \end{pmatrix}, \]  

(10)

then (9) is equivalent to (7) because

\[ \begin{pmatrix} A_i & B_i \end{pmatrix}^{-1} = \begin{pmatrix} -I_N & T \\ O & -I_M \end{pmatrix}, \]  

(11)

where \( I_N \) and \( I_M \) are the \( N \times N \) and \( M \times M \) unit matrices.

Even when the material has nonlinear properties, it is possible to define \( \partial v^{n+1}/\partial v^n \) and to use it for a rough evaluation of numerical stability and also for the stability analysis of the steady-state field that is static or periodic. However, the strict numerical stability analysis for general nonlinear media is difficult because \( \partial v^{n+1}/\partial v^n \) depends on the field amplitude.

**IV. COMPUTATIONAL RESULTS**

The numerical stability of the space-time subgrid (Fig. 1) is examined. There, the spatial cell size and the temporal step of the coarse grid (main grid) are \( \Delta x \) and \( \Delta w = c\Delta t \), respectively, whereas those of the fine grid (subgrid) are \( \Delta x/2 \) and \( \Delta w/2 \).

**A. Stability in 3D-Space-Time**

To examine the propagation of \((E_x, E_y, B_z)\) on the \((x^0, x^1, x^2)\)-3D space-time grid, its connection to the subgrid is illustrated in Fig. 3. The associated time-marching scheme is presented in (Matsuo et al. 2015).

Figure 2(a) illustrates the corner part of subgrid connection for which the variables \( e_x \) and \( e_y \) are given by (18) and \( d_x \) and \( d_y \) are given by (19); \( \delta \) is a free

![Figure 1: Space-time grid.](image1)

![Figure 2: Periodic allocation of variables.](image2)

![Figure 3: Connection to subgrid.](image3)

![Figure 4: Corner part: (a) non-orthogonal grid, (b) symmetric correction.](image4)
parameter. When \( \delta \neq 0 \), the face for \( e_s \) (or \( e_e \)) is not orthogonal to the edge for \( d_s \) (or \( d_e \)), which causes a numerical error.

Based on the vectorial relation shown in Fig. 4(b), a symmetric correction,

\[
e_s = Z\Delta w [(1-\delta) \ddot{x} - \delta' \ddot{d}_x] \\
e_e = Z\Delta w [(1-\delta) \ddot{y} - \delta' \ddot{d}_y],
\]  

(12)

can be used to avoid asymmetry arising in the impedance matrix. Because the face for \( e_s \) (or \( e_e \)) is slanted along the \( x^0 \)-direction, as in Fig. 3, \( \delta' \) is given by \( \delta + (c_i \Delta w)^2/12 \).

A small 3D space-time grid having spatial domain size of \( 30\Delta x \times 30\Delta x \), and including a subgrid domain of \( 28(\Delta x/2) \times 28(\Delta x/2) \), is used in the numerical eigenvalue analysis with \( \epsilon_r = \mu_r = 1 \). Spatially periodic boundary conditions are imposed.

Figure 5 plots the eigenvalue distribution of \( \partial v^{n+1}/\partial v^n \) without correction when \( \Delta w / \Delta x = 0.5, 0.51 \) and \( \delta = 0.08 \). For \( \Delta w / \Delta x = 0.5 \), all the eigenvalues of \( \partial v^{n+1}/\partial v^n \) are on the unit circle, which implies that the explicit time-marching scheme is stable. When \( \Delta w / \Delta x = 0.51 \), some of the eigenvalues move outside the unit circle [Fig. 5(b)], causing numerical instability.

Figure 6 plots the eigenvalue distribution with the symmetric correction, which does not affect the stability.

The FI method allows slanted edges to be curved [Cf. Fig. 7(a) and (b)], where node positions (●) are unchanged (Matsuo et al. 2015). A further transformation leads to staircase-like edges [Fig. 7(c)]. The edges can be transformed along the temporal direction also [Fig. 8].

Hereon, the space-time grids of Figs. 7(a) and 8(a) are referred to as straight type whereas the grids of Figs. 7(c) and 8(c) are referred to as staircase type. It is difficult for the straight type subgrid connection to locate the subgrid boundary at the planar boundary of two materials, which is possible for the staircase type connection.

Figure 9 plots the eigenvalue distribution using the staircase-type space-time grid without correction for \( \Delta w / \Delta x = 0.5, 0.51 \) and \( \delta = 0.02 \). Figure 10 plots the eigenvalue distribution with symmetric correction. Similar distributions in Figs. 9 and 10 to those in Figs. 5 and 6 show that the space-time FI method is conditionally stable.

The effect of grid type and symmetric correction on the computational accuracy is examined in Appendix B.

\[ \begin{array}{c}
\text{(a)} \\
\text{(b)}
\end{array} \]

B. Stability in 4D Space-Time

Figure 11(a) illustrates a 4D connection to the subgrid of straight type, where \( \delta \) is a free parameter. Similar to the case for the 3D subgrid, the edges and faces can curve resulting in a staircase-type grid [Fig. 11(b)].
A small 4D space-time grid having spatial domain size of 12Δx × 12Δx × 12Δx including a subgrid domain of 8(Δx/2) × 8(Δx/2) × 8(Δx/2) (see Fig. 12) is used in the numerical analysis of eigenvalues; spatially periodic boundary conditions are imposed. Figures 13 and 14 plot the eigenvalue distribution using the straight- and staircase-type grids, respectively. The 4D space-time FI scheme is conditionally stable because for small-valued Δw/Δx all the eigenvalues of $\partial w^{\nu+1}/\partial w^{\nu}$ are on the unit circle. The staircase-type grid type allows a temporal step size of $\Delta w / \Delta x = 0.4$ for stable explicit time marching whereas the straight-type grid suffers from instability $\Delta w / \Delta x \geq 0.34$.

**Figure 12:** Small space-time grid for eigenvalue analysis.

**Figure 13:** Eigenvalues of $\partial w^{\nu+1}/\partial w^{\nu}$ with 4D straight-type grid for $\Delta w / \Delta x$ is (a) 0.32 and (b) 0.34.

**Figure 14:** Eigenvalues of $\partial w^{\nu+1}/\partial w^{\nu}$ with 4D staircase-type grid for $\Delta w / \Delta x$ is (a) 0.4 and (b) 0.42.

**V. CONCLUDING REMARKS**

A scheme for the numerical analysis of stability of the space-time FI method is presented. The 3D and 4D subgrid schemes using the space-time FI method are conditionally stable, where a symmetric correction for the constitutive relation does not induce numerical instability. The staircase-type 4D space-time subgrid allows a larger time-step than the straight-type subgrid.

**APPENDIX**

**A. Geometrical Formulation of Space-Time FI method**

The geometrical formulation of the 3D space-time FI method is derived, where the coordinates are $(x^0, x^1, x^2)$ and the propagation of fields $(E_i, E_2, B_3)$ is described:

$$F = cB_1 dx^1 dx^2 + E_2 dx^2 dx^0 - E_1 dx^0 dx^1,$$
$$E = H_2 dx^0 - cD_2 dx^1 + cD_1 dx^2.$$  \hspace{1cm} (13)

Compared with the 4D case, $E dx^3$ corresponds to $F$ in (2). Let arrays $\{n\}$, $\{s\}$, $\{p\}$, and $\{v\}$ denote the sets of nodes, edges, faces, and volumes in the 3D space-time primal grid, respectively. These are related by incidence matrices $[G]$, $[C]$, and $[D]$ as:

$$\partial \{s\} = [G]\{n\}, \partial \{p\} = [C]\{s\}, \partial \{v\} = [D]\{p\}$$ \hspace{1cm} (14)

where $\partial$ denotes the restriction to the boundary. Similarly, the sets of nodes, edges, faces, and volumes in the dual grid are related as:

$$\partial \{g\} = [G]\{i\}, \partial \{p\} = [C]\{g\}, \partial \{v\} = [D]\{g\}.$$ \hspace{1cm} (15)

The $k$-th face $p_{(k)}$ on the primal grid and its corresponding edge $\xi_{(k)}$ on the dual grid are written:

$$p_{(k)} = p_{(k)}^0 dx_1 dx_2 + p_{(k)}^1 dx_2 dx_0 + p_{(k)}^2 dx_0 dx_1,$$
$$\xi_{(k)} = \xi_{(k)}^0 dx_0 + \xi_{(k)}^1 dx_1 + \xi_{(k)}^2 dx_2.$$ \hspace{1cm} (16)

Using $p_{(k)}^i$ and $\xi_{(k)}^i$, the area vector $p_{(k)}$ and the edge vector $\xi_{(k)}$, are defined as

$$P_{(k)} = (p_{(k)}^0, p_{(k)}^1, p_{(k)}^2), \quad \xi_{(k)} = (\xi_{(k)}^0, \xi_{(k)}^1, \xi_{(k)}^2).$$ \hspace{1cm} (17)

Corresponding to $p_{(k)}$ and $\xi_{(k)}$, the variables for the space-time FI method is given as

$$f_{(k)} = \int_{\sigma_{(k)}} F = p_{(k)}^0 cB_1 + p_{(k)}^1 E_2 - p_{(k)}^2 E_1,$$
$$\xi_{(k)} = \int_{\sigma_{(k)}} E = \xi_{(k)}^0 H_2 + \xi_{(k)}^1 cD_2 + \xi_{(k)}^2 cD_1.$$ \hspace{1cm} (18)
where the subscript ‘[k]’ denotes an averaged value on \( p_{(i)} \) or \( S_{(i)} \). Equation (4) is rewritten as
\[
c_gS_{(i)}^0 [p_{(i)}^0]^* = -S_{(i)}^1/c [p_{(i)}^1]^* = -S_{(i)}^2/c [p_{(i)}^2]^* = \kappa_{(i)} \cdot \tag{20}
\]
and implies that \( S_{(i)} \) is orthogonal to \( p_{(i)} \) by the Lorentzian metric but may be non-orthogonal to \( p_{(i)} \) by the Euclidean metric. Figure 15 illustrates the geometrical relation between \( p_{(i)} \) and \( S_{(i)} \), where \( p_{(i)}^* / \kappa_{(i)} \) denotes the inner product using the Euclidean metric.

From (18)–(20), \( f_{(i)} \) and \( g_{(i)} \) are related by impedance \( Z_{(i)} \):
\[
f_{(i)} = z_{(i)} g_{(i)} \tag{21}
\]
where
\[
z_{(i)} = Z_{(i)} / \kappa_{(i)} \tag{22}
\]
In integral form, Maxwell’s equations (1) without source terms are
\[
[D] \{f\} = 0 , \quad [C] \{g\} = 0 , \tag{23}
\]
where \( \{f\} \) and \( \{g\} \) consist of the variables defined by (18) and (19). In matrix form,
\[
\{f\} = [z] \{g\} , \tag{24}
\]
where \( [z] \) is the diagonal matrix formed with elements (22).

If vectors \( p_{(i)} \) and \( S_{(i)} \) are represented as in Fig. 15, \( S_{(i)} \) may have the opposite direction [Fig. 15(b)]. This fact is due to the relation (20) and results in the relation
\[
[C] = [C]^* . \tag{25}
\]
The matrix operator \( ^* \) is defined as
\[
{c_{ji}} = \begin{cases} c_{ji} & (c_{ji} \neq 0, p_{(i)}, S_{(i)} > 0) \\ -c_{ji} & (c_{ji} \neq 0, p_{(i)}, S_{(i)} < 0) \\ 0 & (c_{ji} = 0) \end{cases} \tag{26}
\]
where \( c_{ji} \) and \( c_{ji}^* \) are the respective elements of \( [C] \) and \( [C]^* \) corresponding to the pair \( p_{(i)} \) and \( S_{(i)} \).

Equations (22), (23), and (25) determine the space-time Maxwell grid equations
\[
\left( [D] / [C]^* [z] \right) \{f\} = 0 \cdot \tag{27}
\]
By modifying the impedance matrix, another formulation is possible, where relation \( [C] = [C]^* \) holds. The modified impedance matrix \( [z^*] \) is defined as
\[
z_{(i)}^* = \begin{cases} z_{(i)}^* & (p_{(i)}, S_{(i)} > 0) \\ -z_{(i)}^* & (p_{(i)}, S_{(i)} < 0) \end{cases} \tag{28}
\]
