sacrificial hydrogen acceptor (Table 1, entry 1). After the reaction mixture was stirred at 28 °C for 9 hours, a mixture of the dehydrogenative borylation products **3a** and **4a**, and the hydroboration product **5a** was formed in a ratio of **3a:4a:5a** = 15:5:80, albeit in 20% total yield. The hydrogenation of **1a** also occurred as a side reaction. Next, various ligands were examined using $[\text{Rh}(\text{cod})_2]\text{BF}_4$ as the catalyst precursor. Whereas the use of simple phosphine ligands such as PPh_3 and dppe yielded preferentially the hydroboration product **5a** (entries 2 and 3), P-N bidentate ligand (**L1**) gave a better product selectivity for **3a** (**3a:4a:5a** = 40:2:58) (entry 4). A commercially available P-N bidentate ligand, Pr-Foxap ,^[15] exhibited a dramatic effect to favor the formation of **3a**.^[16] After chromatographic purification, the product **3a** was obtained as a mixture with **4a** and **5a** (**3a:4a:5a** = 91:3:6) in 86% total yield (entry 5).^[17] The *E/Z* ratio of **3a** was 85:15. The counterions of rhodium(I) complexes also affected the product selectivity. The tetraphenylborate complex $[\text{Rh}(\text{cod})_2]\text{BPh}_4$ showed a comparable product selectivity (**3a:4a:5a** = 93:3:4), but the hexafluorophosphate complex $[\text{Rh}(\text{cod})_2]\text{PF}_6$ resulted in a lower product selectivity (**3a:4a:5a** = 28:3:69) (entries 6 and 7). While the neutral complex $[\text{RhCl}(\text{cod})]_2$ is known as the effective precursor for the dehydrogenative borylation of styrene,^[8a,c] it gave a result inferior to $[\text{Rh}(\text{cod})_2]\text{BF}_4$ in terms of both yield and product selectivity (entry 8). Furthermore, the choice of hydrogen acceptor was important. When norbornadiene or styrene was used as the hydrogen acceptor, the yield of **3a** markedly decreased (entries 9 and 10).^[18]

Although it is difficult to explain the reaction pathway leading to alkenyl boronate **3** from aliphatic terminal alkene **1** and HBpin (**2**), a possible mechanism is depicted in Scheme 1. It is similar to the one proposed by Hartwig et al. for the iridium(I)-catalyzed dehydrogenative silylation using norbornene as the hydrogen acceptor.^[19] Oxidative addition of the B–H bond of **2** onto rhodium(I) affords the boryl(hydride)rhodium species **A**. Subsequent insertion of the alkene **1** into the Rh–B bond of **A** takes place to give the alkyl-rhodium intermediate **B**. The initial conformer undergoes rotation along the C–C bond axis to form the other conformer **C**. Then, syn β -hydride elimination furnishes the (*E*)-isomer of alkenyl boronate **3**. (Dihydride)rhodium species **D** reacts with norbornene to

generate an active rhodium(I) species together with norbornane.^[17,20] The strained structure of norbornene enhances the reactivity toward **D**.^[18] Therefore, hydroboration of norbornene is preferred over the alkenyl pinacolboronate **3a**.

The following experiments were carried out in order to obtain mechanistic insights into the stereoselectivity. First, the rhodium(I)-catalyzed reaction of 4-phenylbut-1-ene (**1a**) with HBpin (**2**) was monitored by GC after 20 min (Eq 1). The *E/Z* ratio of **3a** was 74:26 at 18% conversion of **1a**. Thus, the *E/Z* ratio of **3a** changed during the reaction (vs. 9 hours; Table 1, entry 5).

Secondly, the purified (*Z*)-isomer of **3a** was subjected to the standard reaction conditions using oct-1-ene (**1c**) as a substrate (Eq 2). The *E/Z* isomerization of **3a** took place to give an *E/Z* = 57:43 mixture. Based on these results, the stereochemistry seems to be subject to thermodynamics rather than kinetics.

A variety of terminal alkenes **1** were subjected to the dehydrogenative borylation with HBpin (**2**) by using a combination of $[\text{Rh}(\text{cod})_2]\text{BF}_4/\text{Pr-Foxap}$ and norbornene (Table 2). Mono-substituted alkenes **1b–f** readily reacted with **2** to afford the corresponding alkenyl pinacolboronates **3b–f** with good yields, product selectivities, and *E/Z* ratios (entries 1–5), whereas the reactions of 3-*tert*-butylprop-1-ene (**1g**) and cyclohexylethene (**1h**) were rather sluggish, probably owing to the steric hindrance (entries 6 and 7). Functional groups such as siloxy, chloro, methoxycarbonyl, and epoxy groups were tolerated in the alkyl chain under the reaction conditions (entries 8–13). The reaction of 1,1- and 1,2-disubstituted alkenes such as 1,1-diethylethene and cyclohexene failed to give the desired alkenyl pinacolboronates.^[21] Therefore, in the case of 2-methylhexa-1,5-diene (**1o**) including 1,1-disubstituted alkene moiety, only the terminal mono-substituted alkene moiety underwent the dehydrogenative borylation to afford mono-borylated product **3o** (entries 14). Similarly, 4,8-dimethylnona-1,7-diene (**1p**) produces selectively mono-borylated product **3p** (entry 15). 1,1-Dimethylbuta-1,3-diene (**1q**) was also a suitable substrate to give the corresponding dienyloboronate **3q** with high product selectivity and *E/Z* ratio (entry 16). Allyltriphenylsilane (**1r**) and 4-methoxystyrene (**1s**) successfully participated in this reaction (entries 17 and 18). The (*E*)-isomer was exclusively formed with **3s**.

Scheme 1. Plausible catalytic cycle for the dehydrogenative borylation.

Table 2: Rh^I-catalyzed dehydrogenative borylation of various terminal alkenes **1** with HBpin (**2**).^[a]

The resulting alkenyl pinacolboronates were useful intermediates in organic synthesis.^[1b] Thus, we examined one-pot two-step transformations via the formation of alkenyl boronates, saving time and solvents required for a workup/purification procedure. After volatile materials in the reaction mixture of aliphatic terminal alkene **1a** with HBpin (**2**) were removed under reduced pressure, aqueous THF solution of sodium perborate was directly added to the residue including alkenyl pinacolboronate **3a**. Oxidation of **3a** occurred to form the corresponding aldehyde **6** in 60% isolated yield based on **1a** (Scheme 2). Formally, this one-pot reaction achieved anti-Markovnikov oxidation of terminal alkenes at ambient temperature,^[22] complementing the Wacker-Tsuji oxidation by palladium catalyst. Furthermore, it avoids the need for two oxidation steps to convert a hydroboration product (alkyl boronate) of an alkene into an aldehyde.

Scheme 2. One-pot synthesis of aldehydes from terminal alkenes.

We have recently reported an enantioselective synthesis of anti-homoallylic alcohols from terminal alkynes, HBpin, and aldehydes via the formation of alkenyl pinacolboronates, which act as γ -substituted allylboron species.^[23] Thus, the residue including alkenyl pinacolboronate **3b** was treated with benzaldehyde (**7**) in the presence of [Ir(cod)₂]/BF₄/PCy₃ and (*R*)-TRIP in 1,2-dichloroethane (DCE). Anti-homoallylic alcohol **8** was obtained with high diastereo- and enantioselectivities (Scheme 3). The above-mentioned reactions provide efficient methods to directly functionalize aliphatic terminal alkenes in one pot.

Scheme 3. One-pot synthesis of homoallylic alcohols from terminal alkenes. (*R*)-TRIP = (*R*)-3,3'-Bis(2,4,6-triisopropylphenyl)-1,1'-binaphthyl-2,2'-diyl hydrogenphosphate.

In summary, we have disclosed that a combined use of a cationic rhodium(I) complex, ^tPr-Foxap, and norbornene enables the facile preparation of alkenyl pinacolboronates from aliphatic terminal alkenes and HBpin at ambient temperature. Since terminal alkenes are more easily accessible and often more desirable starting materials than terminal alkynes, the reaction represents an interesting alternative to alkyne hydroboration. Based upon the dehydrogenative borylation reaction, the one-pot syntheses of aldehydes and homoallylic alcohols starting from terminal alkenes have also been realized. Further studies

to elucidate the mechanism of this reaction and to expand its utility are in progress.

- [16] When the reaction of **1a** with **2** was conducted using (rac)-[2-(oxazolin-2'-yl)ferrocenyl]diphenylphosphine (the Pr group of Pr-Foxap is lacking) in place of Pr-Foxap, the yield of **3a** significantly decreased. The result suggests that the bulkiness of the Pr group would be one of the important factors.
- [17] Norbornane (ca. 83%), 2-norbornyl pinacolboronate (ca. 46%), and butylbenzene (ca. 3%) were also formed (GC yield).
- [18] When the reaction was conducted in the absence of norbornene, no alkenyl pinacolboronate **3a** was formed. The hydroboration product **5a** and the diboration product **9a** were formed in 41% and 44% yields, respectively. These results indicate that norbornene plays a crucial role of inhibiting over-reduction of **3a**. When cyclohexene was used in place of norbornene, it was too unreactive to act as the hydrogen acceptor, giving **5a** and **9a** as the major products.

COMMUNICATION

Aliphatic terminal alkenes react with pinacolborane at ambient temperature in the presence of $[\text{Rh}(\text{cod})_2]\text{BF}_4/\text{Pr-Foxap}$ and norbornene to produce dehydrogenative borylation compounds as the major product. The reaction is applied to the one-pot syntheses of aldehydes and homoallylic alcohols from aliphatic terminal alkenes.
