Abstract

Acute occlusion of the infrarenal abdominal aorta is a vascular catastrophe, and the prognosis remains poor. This report describes a 52-year-old man with acute occlusion of the abdominal aorta following acute myocardial infarction. He was successfully treated with a transfemoral embolectomy with the use of a Fogarty catheter. The postoperative course was uneventful.

Introduction

Arterial embolism is a relatively common clinical problem. Aortic saddle embolus is the most common cause of acute aortic occlusion that is a catastrophe which usually occurs in patients with heart disease. We report a case of acute aortic occlusion following acute myocardial infarction successfully treated by embolectomy.

Case report

On June 8, 1988, a 52-year-old man was hospitalized due to chest oppressive sensation of 24 hours’ duration. Physical examination revealed a blood pressure of 136/80 mm Hg and a regular pulse of 120 per minute. The chest roentgenogram showed pulmonary congestion and moderate cardiomegaly with a cardiothoracic ratio of 0.61. The electrocardiogram showed a normal sinus rhythm with an extensive acute anterior wall myocardial infarction. Coronary angiography showed complete occlusion of the proximal left anterior descending coronary artery. The left circumflex and right coronary arteries appeared normal. Left ventricular angiography was not performed. A percutaneous intra-aortic balloon pump catheter was inserted via the right femoral artery for circulatory assistance and removed percutaneously on June 13. Counterpulsation was continued for five days. Four hours after removal of the balloon, the patient experienced
sudden severe pain in both lower extremities which were cold and pulseless. Bilateral iliac artery occlusion was suspected. An intravenous bolus of 7000 U of heparin was given. An emergency abdominal aortogram demonstrated complete occlusion of the abdominal aorta at the level of the aortic bifurcation with poor collateral vessels to the lower extremities (Fig. 1).

On June 13, 1988, three hours after the onset of symptoms bilateral groin incisions were made. The common, superficial and deep femoral arteries were isolated. An arteriotomy was performed on both common femoral arteries which were occluded with fresh thrombus, and a transfemoral thrombectomy of the abdominal aorta, iliac, and femoral arteries with the use of a Fogarty balloon catheter. After removal of the thrombus, the arteriotomies were closed.

Good femoral and popliteal pulses were restored, and the postoperative course was uneventful. Cardiac catheterization and angiography were performed on the 32nd postoperative day. Coronary angiography showed complete occlusion of the proximal left anterior descending coronary artery. Left ventricular angiography showed a large aneurysm of the left ventricle. Abdominal aortography revealed excellent contrast filling and flow in the abdominal aorta and iliac arteries (Fig. 2). The patient was discharged asymptomatic on the 45th day.

On November 1, 1988, an elective operation was performed for the left ventricular aneurysm. Mural thrombi were noted in the left ventricle (Fig. 3). The postoperative course was uneventful.
Discussion

The most common cause of acute occlusion of the infrarenal abdominal aorta is an aortic saddle embolus. Such emboli represent approximately 10% of all peripheral emboli. Although the heart is the most common source of the embolus, arteriosclerotic heart disease with either atrial fibrillation or recent myocardial infarction has replaced rheumatic heart disease as the most common cause of embolism. Embolism is most likely in the first three weeks after myocardial infarction. In our case embolism occurred six days after an extensive anterior myocardial infarction. At the time of operation for post-infarction aneurysm of the left ventricle, five months after the embolectomy, mural thrombi were found in the left ventricle, and the origin of the embolus was ascertained (Fig. 3).

Patients with arterial emboli are prepared for surgery as rapidly as possible. Bilateral transfemoral catheter embolectomy under local anesthesia is the usual choice for acute aortic
occlusion$^4,9)$. Because our patient was already in the hospital for acute myocardial infarction when embolization occurred, he was promptly operated on three hours after the onset of symptoms and survived with good function of the extremities. However, perioperative mortality and the need for amputation remain high, especially in patients with acute aortic occlusion.
