

A HISTOLOGICAL STUDY ON THE AFFERENT INNERVATION OF THE LARGE BLOOD VESSELS

by

YAT MAN CHENG

From the 2nd Surgical Division, Kyoto University Medical School

(Director: Prof. Dr. YASUMASA AOYAGI)

Received for publication Nov. 17, 1956

I. INTRODUCTION

Histological studies concerning the innervation of blood vessels have been reported by many investigators. MICHAILOW (1908) described an outer plexus in the adventitia (Adventitial Nervengeflecht), a deeper plexus at the border between adventitia and media (Grenzervengeflecht), and the deepest plexus in the media (Muskelnervengeflecht). GLASER (1914) and MITSUI (1929) also described 3 concentric zones of nervous networks; the deepest of which extended to the intima. On the other hand, both HIRSCH (1925) and STOEHR Jr. (1928) observed a plexus on the surface of the circular muscle, but denied the existence of nerve fibres in the deeper layer of the musculature. BOEKE (1932) had emphasized the abundance of nerve fibres forming a dense, intricate plexus throughout the entire layer of the media. NONIDEZ (1936) described nerve fibres in the superficial layers of the media, but denied the existence of a plexiform nervous structure throughout the media, as described by BOEKE.

Next, studies concerning the afferent nerve terminations have been described by relatively few investigators. These terminations are known as presso-receptors, and are confined to certain areas; such as the carotid sinus, aortic arch, proximal portion of the aorta and the pulmonary artery. They were described by TELLO (1924), MITSUI (1929), SUNDER-PLOSSMANN (1930), MURATORI (1932), TAKINO (1933), STOEHR Jr. (1933), NONIDEZ (1935), NETTLESHIP (1936) and SETO (1937). These receptive structures are described as diffuse arborizations, the branches of which were slender and end in fine terminal nets. Most of these structures were limited to the adventitia, and only a few of them were described in the media.

It is a well known fact that the staining of the vascular nerves is a difficult task. A long period of fixation often gives rise to various artefacts, which will mislead us to erroneous interpretation of the nervous structures.

Recently, in 1954, WEDDELL introduced the application of "spreading factors" in the demonstration of tissue neural elements. He stated that the use of "spreading factors" assists the process of rapid and even tissue fixation and thus eliminates artefacts, which are known to result from the slow penetration of fixatives. Similarly, it makes the various agents used to stain or impregnate nerve fibres after fixation penetrate more rapidly and homogeneously and the results obtained are thus far

more uniform. Moreover, in the case of silver impregnation, it also renders reticular and collagen fibres nonargyrophil.

Accordingly, this new process is applied to the present study, in which the author searched for the afferent nerve terminations in the middle portion of the common carotid artery, abdominal aorta and vena cava, which are to date still unexplored.

II. MATERIALS AND METHODS

All the materials were obtained from adult dogs.

Under general anaesthesia with sodium isomytal, the necessary blood vessels were exposed, and into the walls of which 2 to 3 cc. of hyaluronidase solution were injected (1,000 T. R. units solved in 1.0 cc. physiological saline). After 20 minutes, the animal was sacrificed by bloodletting, and the injected portion of the necessary blood vessels were taken out and fixed in 15% neutral formol solution. On the 3rd day of fixation, the specimens were sliced with the freezing microtome into frozen sections of 35~40 μ thickness. The specimens were sliced in cross sections and longitudinal sections. The frozen sections were further fixed for 2~3 days, and were submitted to impregnation.

For impregnation, JABONERO'S silver carbonate method was employed. The procedure is as follows:-

- 1, Wash the section with distilled water for one hour.
- 2, Immerse in 20% silver nitrate solution sheltered from light for 1 hour. In the summer season the time can be shortened, and prolong the time in the winter season.
- 3, Wash in distilled water for 30 seconds.
- 4, Place in 20% neutral formol solution; this solution is prepared by diluting the mother neutral formol with running water, and placed in 5~6 plates. The sections are transferred to these plates one by one until the white precipitation disappears. This process must be completed within 10 minutes.
- 5, Wash in distilled water for 1 minute, during which time the sections are vigorously stirred.
- 6, Prepare 2 plates of silver carbonate solution. To one of them add 3~4 drops of ammonia, and a slice is placed for testing. If the slice gradually takes gold yellow color within 30~60 seconds, the same amount of ammonia is added to the other plate, and the whole sections are placed in it. The sections gradually change from yellow to deep tobacco brown within 5~10 minutes. If the section turns yellow too quick, add more drops of ammonia; if the contrary, reduce the amount of ammonia.
- 7, Wash in distilled water for 5 minutes.
- 8, Differentiate in acetic water (3 drops of acetic acid in 1 cc. of distilled water) for 2~3 minutes. The sections turn from dark brown to gold yellow.
- 9, Wash in distilled water for 3 times.
- 10, Place in 0.2% gold chloride solution for 10 minutes.

11, Fix in 5% sodium thiosulfate solution.

12, Wash, dehydrate and mount in balsam.

The silver carbonate solution is prepared in the following way: To 50 cc. of 20% silver nitrate solution an excess amount of saturated solution of sodium carbonate is added to produce milky yellow precipitate of silver carbonate. The precipitate is washed thoroughly with distilled water. Decant, and all the precipitate is dissolved with the least necessary amount of ammonia. Add 250 cc. of distilled water to the solution, and preserve in a brown flask. The solution is preferably to be stored in dark cool place, and it is available for several months. An important point on the preparation of this solution is that the addition of ammonia should be suspended just before all the silver carbonate precipitates dissolve completely.

III. MICROSCOPICAL OBSERVATION

In 1932 STOEHR Jr. and REISER described the peripheral pattern of the autonomic nerve system as a fine network structure, which they have nominated "Terminalreticulum". Similarly, JABONERO (1953) described "système des fibres nerveuses protoplasmiques", which is a fine network structure enclosed in a band of protoplasm. These nervous structures form a closed network, and never terminate in free endings. In agreement with this theory, H. SETO insisted that the nerve fibres, which terminate freely in the periphery without forming the "Terminalreticulum", should be considered as sensory nerves, and that these sensory nerves could be easily differentiated from the autonomic nerves by their thickness.

In the adventitia, an abundance of JABONERO's syncytium nerveux is observable (Figs. 1 and 2), but though some hundreds of preparations have been inspected, none of them showed any trace of the network structure in the media and intima. A) Common carotid artery.

A thick myelinated nerve fibre running along in the adventitia abruptly changes its course and proceeds into the media in a perpendicular or an oblique direction (Figs. 3 and 4). There are some 7 to 12 concentric undulatory layers of elastic fibres according to the thickness of the vascular wall. These elastic fibres remain unstained and lucid. The nerve fibre after entering the media gives off branches along the elastic fibres at the outer layer of the media (Fig. 5). It proceeds further towards the inner layer and again gives off branches along the elastic fibres (Fig. 6), and finally it terminates freely in the connective tissue between the smooth muscle cells. No direct contact between the termination and the muscle cell is observable (Figs. 7 and 8). By way of the above described ramification, nerve fibres running in various depths can be observed (Fig. 9). Each nerve fibre running along the elastic fibres gradually decreases its thickness, and terminates as a tapering ending (Figs. 10 and 11). Occasionally, some varicosities and bead-like swellings are observed in the midway, and a loop formed near the termination (Figs. 12, 13 and 14). Rarely, a complicated arborization is observed (Fig. 15). As a rule a branch runs along a certain layer of the elastic fibres and terminates in the vicinity, but sometimes it deviates from its course and proceeds towards another

layer (Figs. 16 and 17).

The above described nerves are observed in cross sections. In longitudinal sections a thick nerve fibre is seen running vertically along the major axis in the media (Fig. 18).

These intrinsic vascular nerves distribute over the outer 1/2 to 2/3 layer of the media. In the far inner layer and in the intima there are no traces of any neural element observable.

B) Abdominal aorta.

In the media of the abdominal aorta the same pattern of nerve distribution is observed as in the case of the common carotid artery. Namely, one or more nerve fibres enter into the media from the adventia giving off branches, and proceed towards the inner layer (Figs. 19, 20 and 21). Each branch runs along the elastic fibres for a rather long distance, and terminates freely in the connective tissue without forming any specific end structures (Figs. 22, 23 and 24). Sometimes, the branch further ramifies in due course (Fig. 25). In rare occasions, the fibres form a loop (Fig. 26), or terminate in complicated arborizations (Fig. 27).

Next, in longitudinal sections nerves are seen running in a longitudinal direction with reticulated swellings and varicosities, which are characteristics of the sensory nerves (Figs. 31 and 32). There are also branches running in horizontal directions (Figs. 28 and 33).

In the case of the abdominal aorta, the nerve distribution is also limited to the outer 1/2 to 2/3 layer of the media, and no trace of any neural element is observed further than this limit. Also the network structure of STÖENK'S "Terminalreticulum" is not observed in the entire musculature.

From the above stated observations a pattern of the intrinsic nerve innervation of the arterial wall can be assumed as shown in the schema (Fig. 34).

C) Vena cava inferior.

The nerve distribution in large veins is far more scarce than the large arteries, but the author has been able to pursue a similar thick wavy nerve fibre to the endothelial layer of the intima.

Bundles of thick nerve fibres can be seen circling the vein in the thick layer of the adventitia (Fig. 29). Then, one of the nerve fibres penetrates into the media (Fig. 30), and continues its course along the media (Figs. 35 and 36). When it nears its termination, the fibre abruptly turns its course towards the intima and terminates freely, without forming any specific terminal structure, under the endothelial layer of the intima (Figs. 37, 38 and 39). Only in one case has the author observed a forked termination in the intima (Fig. 40).

There are few or no elastic fibres existing in the thin muscular layer, and the nerve fibre does not ramify as seen in the arteries.

Supplement: Afferent vascular nerve of human popliteal vein.

The material of this specimen was obtained from an adult female patient suffering from sarcoma of the femur. Hyaluronidase solution was injected into the wall of the popliteal vein in the same manner as previously described. This was perfo-

removed immediately after the leg was amputated.

As it is generally known that the larger veins of the extremities have a thicker layer of musculature than those in the abdominal cavity, the author has observed a more abundant nerve supply than in the vena cava. Unfortunately, in exposing the vein the author must have stripped off the adventitial tissues. Consequently, the state of nerve distribution in the adventitia was not revealed.

In the media quite near the middle layer of the musculature, thick undulated nerve fibres can be seen running in a circular direction for quite a long distance. These nerve fibres proceed alongside the muscle bundle or in the connective tissues in between the muscle bundles, and terminate freely without forming any specific structure at the end. Varicosities and reticular swellings can also be observed along its course.

In this specimen nerve fibres are seen only in the media, and the author has been unable to detect any nerve terminations in the intima, as in the case of the vena cava. (Figs. 41, 42, 43, 44 and 45).

IV. EXPERIMENTAL OBSERVATIONS ON THE AFFERENT VASCULAR INNERVATION

Orsu of our laboratory has, in his study on the visceral afferent innervation, revealed the fact that visceral sensory nerve fibres have their nerve cells in the spinal ganglia of the dorsal roots of the spinal cord; the postganglionic fibres have no interposing nerve cells till their terminations. Likewise, the afferents in the vagus nerve also have no interposing cells distal to the jugular and nodular ganglions. According to this fact, Orsu and many other investigators of our laboratory have been able to determine the source of the sensory nerves in various visceral organs by performing vagotomy in which, according to WALLER'S law, these sensory nerves showed secondary degeneration.

The afferent vascular innervation was assumed to be similar to those of the visceral organs; in fact, the nerve fibres observed in the media and the intima of the vascular wall, have a close resemblance to those of the visceral sensory nerves.

Hence, vagotomy and posterior rhizotomy were performed to prove experimentally that the vascular nerves, which have been described, are sensory in nature, and also to determine their source of distribution.

Adult dogs were used in the experiment.

A) Vagotomy.

About 2 cm. of the right vagus trunk was resected distal to the ganglion nodosum. Specimens were taken 6½ days after operation, and were prepared as described previously.

Degenerated nerve fibres were observed in the media of the abdominal aorta. The axis-cylinder had broken down, and gave an appearance of a string of granules or beads along the wavy layer of the elastic fibres, or scattered granules in the connective tissues (Figs. 46 and 47). On the other hand, there were nerve fibres which remained intact in the media. These nerve fibres are probably of the nerves

from the posterior roots of the spinal cord. In the case of bilateral vagotomy performed in the thorax distal to the anastomosis of both of the vagus nerves, similar degeneration was observed in the media (Fig. 48).

In the media of the right common carotid artery, though granular degenerations were not observed, deeply impregnated nerve fibres with strong swelling, and also nerve fibres with vacuoles and partial severance were observed (Figs. 49, 50 and 51). These appearances may be considered as the early phase of degeneration.

B) Posterior rhizotomy.

The spinal cord was exposed by laminectomy, and the dorsal roots were carefully separated through the ganglia. The dorsal roots were resected bilaterally at the point distal to the ganglia. Th. 9, 10 and 11 were resected in this experiment, according to the physiological result of K. TUNEKAWA of our laboratory.

Specimens were taken from the abdominal aorta 3 days after the operation. Granular degenerations of the axis-cylinders were observed along the elastic fibres (Figs. 52 and 53). Nerve fibres with strong rugged swellings were also observed (Fig. 54). In the case of the specimen taken 5 days after rhizotomy, degenerated axis-cylinder particles had begun to vanish, and only dim remainders of the granules were observed in the media (Fig. 55). Hence, it may be concluded that the degeneration of the axis-cylinder reaches its maximal stage on the 3rd or 4th day after posterior rhizotomy.

When inspecting the impregnated specimens one may often confuse the silver particles or specks attached to the surface of the specimen with the granular degeneration of the axis-cylinder. Therefore, by impregnation every effort must be exerted to avoid the precipitation of silver particles on the specimens. Obviously, the silver particles or specks are seen on the surface of the specimen, while the degenerated neural elements can also be seen under the surface by moving the focus of the microscope. Moreover, they may be differentiated by the tone of their color. Silver specks give a black color, while the degenerated neural elements give a deep blue-purple color.

From the results of the above experiments, a conclusion is obtained that these intrinsic vascular nerves are afferent fibres, and they are derived from both vagus and dorsal roots of the spinal cord.

V. DISCUSSION

By applying "spreading factors" to the vascular wall prior to impregnation, the author has been able to observe thick nerve fibres with free terminations in the media of the common carotid artery, abdominal aorta and in the intima of the vena cava of adult dogs; also in the media of human popliteal vein.

In achievement of the present study, the author is much indebted to Prof. Dr. G. WEDDELL.

There is an abundance of nerve plexus in the adventitia, and also ganglionic cells have been found by GLASER, MÜLLER, TAKINO, SUNDER-PLOSSMANN, STOEHR Jr. and SETO etc. In the periphery beyond the nerve plexus or the ganglia of the

adventitia, the autonomic nerves (efferent fibres) will form a reticulated structure as STOEHR's Terminalreticulum or JABONERO's syncytium nerveux. From this view point the thick nerve fibres, which terminate freely in the connective tissue of the media, should not be considered as autonomic or efferent nerves.

JABONERO maintained that syncytium nerveux is distributed numerously over the adventitia, but never cross the border of the media. Therefore, no neurofibrilles exist which have direct contact with the smooth muscle cells of the media, and the impulse must be considered to reach the muscle cells via chemical transmission. In fact, in all the specimens not one of them showed any trace of the network structure of the peripheral autonomic nerve in the media or the intima.

But in some occasions a fine slender nerve fibre is seen running beside the thick nerve fibre. These thin fibres are lightly impregnated compared with the thick fibres, and neither reticulated swellings nor varicosities are observed along its course. Their morphological appearance is quite distinguishable from the thick undulated fibres. Should these fine slender fibres be considered as autonomic efferent fibres is a problem still to be studied.

M. CLARA indicated that the morphologic characteristics of the sensory nerve endings are the specific structures which tend to expand its terminal surface. But G. WEDDELL emphasized that the terminal structures of sensory endings are usually free-ending arborizations, and the complicated terminations may be considered as artefacts. The observations obtained in this study quite agree with his opinion.

H. SETO described sensory nerve terminations of simple arborization in the aortic arch and pulmonary artery of human foetus. M. TAKINO described sensory nerve fibres in the media of the pulmonary artery which terminated freely in the connective tissues between smooth muscle bundles. He also stated that these nerve terminations have no direct relation to the muscle cells, and they should be considered as sensory in nature. According to these opinions, the vascular nerves, which the author has observed may also be considered as sensory in nature.

Generally, sensory nerves are considered to have myelin sheaths till the periphery. Myelin sheaths in the adventitia were easily stained, but they were not observed in the media, therefore, it may be considered that the nerve fibre probably loses its myelin sheath in entering the media.

W. ODERMATT was one of the first who conducted an experimental study on vascular sensitivity. He had provoked vascular pain by expanding the artery mechanically. He explained that the pain was due to traction of the sensory nerve terminals in the adventitia. But, on the other hand, barium chloride is known to have a strong vasoconstrictive action, and the strong vascular spasm caused by it also provokes vascular pain. It is reasonable to think that the pain is provoked by the compression of the sensory terminals in the media rather than the traction of the adventitial sensory endings.

The author has not been able to observe any ganglionic cells or Pacinian corpuscles in the adventitia as described by KRAUSE, WOOLARD, RACHMANOW, HIRSCH, STOEHR and SETO etc. These corpuscles are situated at the outer layer of the adventitia or in

the connective tissues surrounding the blood vessel, and in exposing the vessels for the injection of hyaluronidase, the surrounding tissues with the corpuscles in it must have been stripped off.

K. TUNEKAWA of our laboratory has recently succeeded in provoking vascular pain by inserting cardiac catheter with bipolar electrodes at an end into the blood vessels to stimulate electrically from inside. His physiological experiment has revealed that the afferent impulse is conveyed through the vagus and the dorsal roots of the spinal cord. This result coincides with the histological result of the present experiment.

Up to date, sensory terminations of the vein still remain unclarified. H. SETO has reported of observing simple sensory terminations in the media of the vena cava of human foetus. He also stated that these terminations exist only during the foetal stage, and they may disappear after birth. The author has succeeded in discovering thick wavy sensory nerve fibres not only in the media of adult dog's vena cava, but also in the media of adult human popliteal vein.

Blood pressure is known to be regulated through the presso-receptive nerves in carotid sinus, aortic arch and other specific areas, and the author imagines the vascular nerve terminations found besides these portions will also contribute to the regulation of blood circulation.

VI. SUMMARY AND CONCLUSION

Applying the injection of hyaluronidase to the material, and with the silver carbonate impregnation, thick undulated nerve fibres are observed in the media of adult dog's common carotid artery, abdominal aorta and human popliteal vein, and also in the intima of adult dog's vena cava; veins are much less innervated than arteries.

These nerve fibres with some exceptions generally terminate in simple tapering endings in the connective tissues between muscle bundles, and neither complicated terminal structures nor specific end apparati are observed. The distribution of these fibres is of a three dimensional pattern i.e. circular, radial and longitudinal. Although reticulated structure of the "Terminalreticulum" or the "syncytium nerveux" is not observed in the media and intima, fine slender fibres are observed in the media in some occasions. They may be considered as the autonomic efferent fibres, but a definite conclusion is not yet reached. The thick nerve fibres showed secondary degeneration when vagotomy and posterior rhizotomy were performed.

Finally, a conclusion is reached, that these thick nerve fibres are the intrinsic afferent nerves of the vascular wall, and are derived from both vagus and dorsal roots of the spinal cord.

An abstract of this study has been reported by Assist. Prof. Dr. Ch. KIMURA of our clinic at the symposium of the International Society of Neurovegetative Research in Strassburg on 1st Oct. 1955.

I wish to express my deepest gratitude toward Assist. Prof. Dr. Ch. KIMURA for his helpful advice and kind guidance throughout this study.

和文抄録

大血管の求心性神経支配に関する組織学的研究

京都大学医学部外科学教室第2講座 (指導 青柳安誠教授)

大学院学生 鄭 逸 民

Jabonero 氏神経鍍銀法を用い、成犬の総頸動脈、腹部大動脈、下空静脈及び成人の膝窩静脈に於て、その壁内に求心性神経の形態及び分布を検索し、更に成犬の迷走神経並に脊髄後根 (Th. 9~Th. 11) を実験的に切断し、各動、静脈壁内末梢神経軸索の二次的変性を追求し、之等の結果より血管壁の求心性神経支配に関し以下の如き結論を得た。

1) 成犬の総頸動脈及び腹部大動脈の中膜層に於て、太き波状走行を呈する神経繊維を認め、之等の神経繊維は輪状、及び放線状に分布し、更に縦に連絡しているのが認められた。

2) 成犬の下空静脈に於ては、外膜より進入した神経繊維の内膜直下迄達するのが認められた。

3) 成人の膝窩静脈に於ては、比較的厚き中膜の平滑筋束に沿つて波状走行を呈する太き神経繊維が認められたが、内膜には認められなかつた。

4) 静脈に於ける神経分布は動脈に比べて遙かに少

い。

5) 之等神経繊維は、殆んど遊離終末を以つて結締織間に終り、筋細胞との接触或は、細胞内進入は認められなかつた。

6) 外膜に於て Jabonero の云う “Syncytium nerveux” を多数認めたが、中膜及び内膜に於ては網様構造を呈する自律神経性終末を認め得なかつた、然し時に繊細な、神経繊維を中膜に認め、之は或は自律神経性の繊維ではないかと思はれる。

7) 迷走神経及び脊髄後根切断実験に於て、中膜に軸索変性像を認めた。従つて血管壁の求心性神経は、迷走性、脊髄性の二重支配を受けている事が判明した。

8) ヒアルロニダーゼの応用に依り、困難視された。血管神経染色を鮮明に且つ短期間 (一週間) の固定で鍍銀染色する事が出来た。

Fig. 3. Nerve fibre penetrates into media from adventitia. Common carotid artery. Dog. $\times 600$.

Fig. 6. Radial and circular running nerve fibres in the media. Common carotid artery. Dog. $\times 400$.

Figures

Y. M. CHENG.

Fig. 7. Nerve termination in tapering ending in the connective tissue of the media. Common carotid artery. Dog. $\times 100$.

Fig. 10. Nerve termination in tapering ending in the connective tissue of the media. Common carotid artery. Dog. $\times 600$.

Fig. 8. Nerve termination in forked arborization. Common carotid artery. Dog. $\times 900$.

Fig. 11. Nerve terminates in taper ending beside the elastic fibres. Common carotid artery. Dog. $\times 600$.

Fig. 9. Two nerve fibres in different depth of the media. Common carotid artery. Dog. $\times 200$.

Fig. 12. Nerve fibre with varicosities in the media. Common carotid artery. Dog. $\times 600$.

Figures

Y. M. CHENG.

Fig. 13. Nerves with varicosities and loop-like ending in the media. Common carotid art. Dog. $\times 400$.

Fig. 16. Nerve fibre between two layers of elastic fibres. Common carotid artery. Dog. $\times 900$.

Fig. 14. Nerve terminates in loop-like ending. Common carotid artery. Dog. $\times 600$.

Fig. 17. Nerves cross over to other layer of elastic fibres. Common carotid artery. Dog. $\times 400$.

Fig. 15. Nerve ending shows complicate arborization. Common carotid artery. Dog. $\times 600$.

Fig. 18. Verticle running fibre with horizontal branch. Longitudinal section. Common carotid artery. Dog. $\times 600$.

Figures

Y. M. CHENG.

Fig. 19. Nerve fibre running from adventitia into media in oblique direction. Longitudinal section. Abdom. aorta. Dog. $\times 600$.

Fig. 22. Nerve fibre along elastic fibres in the media. Abdom. aorta. Dog. $\times 100$.

Fig. 20. Ramification in the outer layer of media. Abdom. aorta. Dog. $\times 400$.

Fig. 23. Wavy nerve along the elastic fibres in the media. Abdom. aorta. Dog. $\times 600$.

Fig. 21. Radial running nerve fibre with branches in circular direction along elastic fibres. Abdom. aorta. Dog. $\times 900$.

Fig. 24. Wavy nerve terminal with taper ending in connective tissue of the media. Abdom. aorta. Dog. $\times 900$.

Figures

Y. M. CHENG.

Fig. 25. Nerve ramification in media. Abdom. aorta. Dog. $\times 400$.

Fig. 28. Branches in verticle and horizontal directions. Longitudinal section. Abdom. aorta. Dog. $\times 400$.

Fig. 26. Nerve terminal forming a large loop in the media. Abdom. aorta. Dog. $\times 900$.

Fig. 29. Bundle of nerve fibres in adventitia. Vena cava. Dog. $\times 400$.

Fig. 27. Nerve terminal with complicate arborization in the media. Abdom. aorta. Dog. $\times 900$.

Fig. 30. Nerve fibre entering media from adventitia. Vena cava. Dog. $\times 900$.

Y. M. CHENG.

Figures

Fig. 31. Nerve fibre with reticulated swellings and varicosities running in longitudinal direction in the media. Abdom. aorta. Dog. $\times 600$.

Fig. 33. Longitudinal nerve fibre with horizontal branches in the media. Longitudinal section. Abdom. aorta. Dog. $\times 400$.

Fig. 32. Nerve fibre with reticulated swellings running in longitudinal direction in the media. Longitudinal section. Abdom. aorta. Dog. $\times 600$.

Fig. 34. Schema showing the pattern of afferent innervation of arterial wall.

Figures

Y. M. CHENG.

Fig. 35. Circular running nerve fibre in the media. Vena cava. Dog. $\times 600$.

Fig. 38. Nerve termination in the intima. Vena cava. Dog. $\times 900$.

Fig. 36. Circular running nerve fibre in the media. Vena cava. Dog. $\times 900$.

Fig. 39. Wavy nerve termination in the intima. Vena cava. Dog. $\times 900$.

Fig. 37. Nerve termination in the intima, where round nuclei of endothelial cells are observable. Vena cava. Dog. $\times 900$.

Fig. 40. Nerve termination with forked ending in the intima. Vena cava. Dog. $\times 900$.

Figures

Fig. 41. Thick wavy nerve fibre running in circular direction in the media. Popliteal vein. Human. Cross section. $\times 400$.

Fig. 43. Nerve termination in the connective tissue between smooth muscle bundles of the media. Popliteal vein. Human. $\times 900$.

Fig. 42. Thick nerve fibre in the media. Popliteal vein. Human. $\times 900$.

Fig. 44. Thick wavy nerve fibre with varicosities in the media. Human popliteal vein. $\times 400$.

Fig. 45 (a). Long thick wavy nerve fibre with varicosities running in circular direction in the media. Human popliteal vein. $\times 900$.

Fig. 45 (b). Continuation of the nerve fibre in Fig. 45 (a)

Figures

Y. M. CHENG.

Fig. 46. Degenerated axis-cylinder along the elastic fibres 6½ days after vagotomy. Abdom. aorta. Dog. × 900.

Fig. 49. Degenerated nerve fibre showing strong swelling 5 days after vagotomy. Common carotid artery. Dog. × 900.

Fig. 47. Granular degeneration of axis-cylinder scattered in connective tissue of the media. 6½ days after vagotomy. Abdom. aorta. Dog. × 900.

Fig. 50. Degenerated nerve fibre showing strong swelling 5 days after vagotomy. Common carotid artery. Dog. × 900.

Fig. 48. Granular degeneration of axis-cylinder in the media, 7 days after bilateral vagotomy. Abdom. aorta. Dog. × 900.

Fig. 51. Degenerated nerve fibre with vacuoles and partial severance, 5 days after vagotomy. Common carotid artery. Dog. × 900.

Figures

Y. M. CHENG.

Fig. 52. Degenerated axis-cylinder in the media, 3 days after post. rhizotomy. (Th. 9, 10, 11) Abdom. aorta. Dog. × 900.

Fig. 54. Degenerated nerve fibre showing strong rugged swelling, 3 days after post. rhizotomy. Abdom. aorta. Dog. × 900.

Fig. 53. Degenerated nerve fibres in different depth of the media, 3 days after post. rhizotomy. (Th. 9, 10, 11.) Abdom. aortat. Dog. × 900.

Fig. 55. Degenerated axis-cylinder partly absorbed, 5 days after post. rhizotomy. (Th. 9, 10, 11). Abdom. aorta. Dog. × 900.

All microphotographs without retouch.

— SKYLUXMINOR —

- ①スカイルツクス，マイナーは灯径 45cm の小型多灯式無影灯ですが最高 20,000LUX の強照度を發揮致します。
- ②此の強照度もノツプ一つで二段に切換えて照度の調節が出来ますから長時間使用时等，視力の疲労防止が出来ます。
- ③焦点距離の調節もノツプ一つで簡単に出来ます
- ④サーモヒルターが装置してありますから焦点光野は殆んど無熱で御座います。
- ⑤No. 902 “A” は天井から床まで 2.5m (8 尺

2 寸) の高さがあれば取付け可能で，天井取付部を中心として 2.4m 周圓 (灯中心) 何処へでも移動致します。

- ⑥No. 903 はベアリングカスターを持つスタンド型で定位置最大周圓直径 1.7m (灯中心) で，灯を更低に下ろした場合床面から 1.2m (灯下面) 最高に上げた場合 2.3m と云う昇降性能を持っております。
 - ⑦特殊な装置により，1 灯或は 2 灯断線しましても他は点灯しておりますから不安無く使用出来ます。
- ◆使用電球は 24V 25W，スパツタリング球 4 個でございます。
