SUMMARY

EWS-FLI1, a multi-functional fusion oncogene, is exclusively detected in Ewing sarcomas. However, previous studies reported that rare varieties of osteosarcomas also harbor EWS-ETS family fusion. Here, using the doxycycline-inducible EWS-FLI1 system, we established an EWS-FLI1-dependent osteosarcoma model from murine bone marrow stromal cells. We revealed that the withdrawal of EWS-FLI1 expression enhances the osteogenic differentiation of sarcoma cells, leading to mature bone formation. Taking advantage of induced pluripotent stem cell (iPSC) technology, we also show that sarcoma-derived iPSCs with cancer-related genetic abnormalities exhibited an impaired differentiation program of osteogenic lineage irrespective of the EWS-FLI1 expression. Finally, we demonstrate that EWS-FLI1 contributed to secondary sarcoma development from the sarcoma iPSCs after osteogenic differentiation. These findings demonstrate that modulating cellular differentiation is a fundamental principle of EWS-FLI1-induced osteosarcoma development. This in vitro cancer model using sarcoma iPSCs should provide a unique platform for dissecting relationships between the cancer genome and cellular differentiation.

INTRODUCTION

Cancer cells often exhibit similar properties to somatic stem/progenitor cells of the tissue of origin (Reya et al., 2001; Rossi and Weiseman, 2006). Considering that progenitor cells at the developmental stage and somatic stem/progenitor cells in some adult tissues have the ability for self-renewal and/or active proliferation, it has been proposed that maintenance of the stem/progenitor cell state could be a driving force for tumor development (Reya et al., 2001). Osteosarcoma is a representative cancer that exhibits shared features with normal stem/progenitor cells (Luo et al., 2008; Thomas et al., 2004). The late markers of osteogenic differentiation are silenced while the early markers are modestly expressed in osteosarcomas (Luo et al., 2008; Thomas et al., 2004). Moreover, more aggressive phenotypes of osteosarcomas are correlated with features of early osteogenic progenitors (He et al., 2010; Luo et al., 2008), suggesting that defects in the osteogenic differentiation program may play a role in osteosarcoma development and progression. However, the causative aberrations that confer stem/progenitor cell properties on osteosarcoma cells are not fully understood.

EWS-FLI1, a widely recognized fusion oncogene for Ewing sarcomas, is generated by the chromosomal translocation of t(11;22) (q24;q12), which consists of the N-terminal transactivator domain of the EWS gene and the C-terminal ETS DNA binding domain of the FLI1 gene. The resulting EWS-FLI1 fusion protein harbors multiple functions, acting as a transcriptional activator, transcriptional repressor, chromatin modulator, and splicing modulator (Kinsey et al., 2006; Riggi et al., 2014; Selvanathan et al., 2015; Smith et al., 2006). Despite the variety of oncogenic functions of EWS-FLI1, a number of previous studies implied that EWS-FLI1 expression itself is not sufficient to induce Ewing sarcoma (Lin et al., 2008; Miyagawa et al., 2008; Riggi et al., 2008; Tanaka et al., 2015) and that other aberrations may be necessary. Indeed, genetic variants near EGR2 and TARDBP are associated with susceptibility to Ewing sarcoma (Grunewald et al., 2015; Postel-Vinay et al., 2012). Moreover, additional genetic mutations, such as TP53, CDKN2A, and STAG2, have been identified in a subset of Ewing sarcomas (Crompton et al., 2014; Tirode et al., 2014). However, it remains unclear whether these mutations are additional driver mutations or passenger mutations and how they contribute to the sarcoma development.

The derivation of induced pluripotent stem cells (iPSCs) demonstrated that mammalian somatic cells can be reprogrammed into pluripotent stem cells (Takahashi and Yamanaka, 2006). It is noteworthy that the reprogramming process does not require any particular alterations to the
genetic information, which makes iPSC technology suitable to study the genotype-phenotype relationship in various diseases (Soldner et al., 2009; Yamashita et al., 2014). Considering that cancer is a genetic disease involving genetic mutations, single nucleotide variants, and structural abnormalities of the chromosome, iPSCs derived from cancer cells are expected to harbor shared genetic abnormalities with the parental cancer cells and therefore should be a powerful tool for dissecting the role of the cancer genome on the phenotype (Semi and Yamada, 2015).

Here, we established a murine EWS-FLI1-induced osteosarcoma model from adult bone marrow stromal cells using a doxycycline (Dox)-inducible-EWS-FLI1 expression system. We revealed that EWS-FLI1 expression inhibits the osteogenic differentiation of sarcoma cells in vitro and in vivo. Moreover, we found that iPSCs derived from the EWS-FLI1-induced osteosarcoma cells exhibit impaired osteogenic differentiation and give rise to sarcoma cells after osteogenic differentiation in vitro in conjunction with EWS-FLI1 expression.

RESULTS

Establishment of EWS-FLI1-Inducible ESCs and Mice

First, we tried to establish an EWS-FLI1-inducible mouse model with locus targeting methods. We established two transgenic systems using embryonic stem cell (ESC) lines containing Dox-inducible EWS-FLI1 alleles that were integrated at different loci by utilizing the KH2 system and Rosa26 targeting vector (Figures 1A, S1A, and S1B) (Ohnishi et al., 2014; Yamada et al., 2013; Beard et al., 2006). In both ESC lines, reverse tetracycline-controlled transactivator (rtTA) is expressed from the Rosa26 locus, and the Tet operator-EWS-FLI1-ires-mCherry construct is integrated into either the 3’UTR of the Col1a1 locus (Rosa-M2rtTA/Col1a1::tetO-EWS-FLI1) or Rosa26 locus (Rosa-M2rtTA/Rosa::tetO-EWS-FLI1). Both ESCs expressed mCherry fluorescence upon treatment with Dox in vitro (Figure 1B). The inducible EWS-FLI1 expression in ESCs was also confirmed by qRT-PCR and western blotting (Figure 1C).

Next, we performed blastocyst injection of EWS-FLI1-inducible ESCs and obtained chimeric mice (Figure 1D and Table S1). Upon Dox treatment, EWS-FLI1 was expressed in a wide variety of organs and tissues of the mice, including the bone marrow and the cortex of the bone where Ewing sarcomas often arise (Figures 1E, 1F, and S1C). Some mice (Rosa-M2rtTA/Col1a1::tetO-EWS-FLI1) died soon after EWS-FLI1 induction, which was accompanied by dysplastic changes of intestinal cells due to impaired differentiation (8 of 14 mice, Figures 1G and S1D). However, despite the long-term induction of EWS-FLI1 (up to 13 months), we did not observe any EWS-FLI1-dependent tumor formation in either system (Figure 1G).

Establishment of EWS-FLI1-Dependent Immortalized Cells with the Dox-Inducible EWS-FLI1 Lentiviral System

Our results suggested that the induction of EWS-FLI1 in adult mice is not sufficient for sarcoma development. Indeed, there is no report that shows the generation of EWS-FLI1-driven sarcomas by the targeted insertion of EWS-FLI1 except for one study that reported the development of myeloid/erythroid leukemia (Torchia et al., 2007). However, previous studies have succeeded in modeling Ewing-like sarcomas in mice when combined with Trp53 deletion or an integrating viral delivery system with the EWS-FLI1 fusion gene, which is consistent with the hypothesis that additional genetic mutations may be required for EWS-FLI1-induced sarcoma development (Castillero-Trejo et al., 2005; Lin et al., 2008; Riggi et al., 2005; Tanaka et al., 2014).

Accordingly, we generated a lentiviral EWS-FLI1 expression vector with the Dox-inducible expression system (Figure 2A). A TetO-EWS-FLI1-ires-Neo cassette was lentivirally transduced into bone marrow stromal cells from adult Rosa26-M2rtTA/M2rtTA mice (3–4 weeks of age). The transduced bone marrow cells were cultured with Dox and G418. The surviving cells were subsequently cultured for 2 months in culture medium containing Dox and G418. Although most cells with EWS-FLI1-inducible alleles did not survive, we nevertheless obtained three immortalized cell lines (EFN#2, EFN#12, and EFN#4; Figure 2B). The three lines expressed EWS-FLI1 mRNA and protein in response to Dox (Figures 2C and 2D) and continuously proliferated under the Dox-containing culture condition (Figure 2B). Upon the withdrawal of Dox, the morphology of two cell lines (EFN#2 and EFN#12) gradually changed to a flat shape and proliferation was inhibited, whereas the third cell line (EFN#4) did not show any evidence of Dox dependency in terms of cellular kinetics (Figure S2A). These observations show that we obtained two EWS-FLI1-dependent immortalized cell lines from murine adult bone marrow stromal cells in vitro.

EWS-FLI1-Dependent Immortalized Cells Formed Osteosarcomas In Vivo

To confirm whether the EWS-FLI1-dependent immortalized cell lines have tumorigenic potential in vivo, we transplanted EFN#2 and EFN#12 into the subcutaneous layer of immunocompromised mice. At 10 weeks after the inoculation, the transplanted mice developed tumors from both cell lines when they were given Dox (16/16 for EFN#2, 2/4 for EFN#12; Figures 2E and 2F), whereas no tumor
formation was observed in mice without Dox administration (0/16 for EFN#2, 0/4 for EFN#12; Figures 2E and 2F). Histological analysis revealed that the tumors consisted of small round blue cells that resembled Ewing sarcomas. However, tumor cells often showed osteoid formation (Figures 2G and S2B) and thus were considered small-cell osteosarcoma, which is a rare subtype of osteosarcomas. In addition, immunohistochemistry showed that the tumor cells expressed EWS-FLI1 and were frequently positive for Ki67, a marker for proliferating cells (Figure S2B).

Establishment of EWS-FLI1-Dependent Osteosarcoma Cell Lines
To further investigate the properties of the EWS-FLI1-induced osteosarcomas in detail, we established EWS-FLI1-dependent osteosarcoma cell lines from subcutaneous
Figure 2. EWS-FLI1-Dependent Small-Cell Osteosarcoma Model by Utilizing the Lentiviral EWS-FLI1 Expression System

(A) Schematic illustrations of the lentiviral EWS-FLI1 expression system. Lentivirus was introduced into bone marrow stromal cells collected from Rosa26-M2rtTA mice. EWS-FLI1-expressing neomycin-resistant cells survived this protocol.

(legend continued on next page)
osteosarcomas in immunocompromised mice inoculated with EFN#2 and EFN#12 cells (SCOS#2 and SCOS#12, respectively). As observed in the primary EWS-FLI1-dependent immortalized cells, the established osteosarcoma cell lines expressed EWS-FLI1 in a Dox concentration-dependent manner (Figure S2C) and actively proliferated in the presence of Dox (Figures 2H and S2D–S2F). After Dox withdrawal, SCOS#2 and SCOS#12 changed their morphology and stopped proliferating (Figure S2D). At the same time, we found increased expressions of p53 and p21, but no increase in β-gal (SAβgal) activity, which is associated with senescence (Figure S2G). Upon re-administration of Dox, the growth-arrested cells reacquired proliferative potential (Figure S2H). The reversible phenotype suggested that EWS-FLI1 depletion results in cell-cycle arrest of the osteosarcoma cells.

Given that the genomic integration of lentivirus might play a role in osteosarcoma development, we also determined the virus integration site of SCOS#2. We identified a single integration at the intergenic region 13 kb downstream of Ca14 (Figure S2I), a location unlikely to act as a genetic driver for sarcoma development.

To evaluate the similarity of the established EWS-FLI1-dependent sarcoma cell lines with human Ewing sarcomas and osteosarcomas, we compared global gene expression profiles of the SCOSs by microarray analysis. We first extracted genes that are specifically upregulated/downregulated in human Ewing sarcomas compared with human osteosarcomas and examined their expression in SCOS#2 and SCOS#12. We found that the gene expression patterns of SCOSs exhibit partial similarities with both human Ewing sarcomas and osteosarcomas (Figure S3A), suggesting that SCOSs have shared characteristics with both Ewing sarcomas and osteosarcomas.

**Depletion of EWS-FLI1 Expression Promoted Osteogenic Differentiation of Osteosarcoma Cells**

To investigate the target of EWS-FLI1, we next compared gene expression profiles between EWS-FLI1-expressing and non-expressing sarcoma cells using SCOS#2 and SCOS#12. Intriguingly, in both cell lines, extracellular matrix and space-related genes, which often include bone and cartilage development-related genes, were significantly enriched in Dox OFF sarcoma cells (for 72 hr) compared with Dox ON EWS-FLI1-expressing sarcoma cells by GO enrichment analysis (Figures 3A, 3B, and S3B). Previous studies proposed that Ewing sarcoma could arise from mesenchymal stem cells (MSCs) (Riggi et al., 2008, 2014; Tirole et al., 2007). Long-term knockdown of EWS-FLI1 with shRNA in Ewing sarcoma cells resulted in cellular differentiation to osteogenic, adipogenic, and chondrogenic lineage, consistent with an MSC origin of Ewing sarcoma (Tirole et al., 2007). Similarly, in the present study, the short-term depletion of EWS-FLI1 in SCOS#2 and SCOS#12 resulted in the promotion of osteogenic differentiation with increased alkaline phosphatase activity (Figure 3C). Notably, after long-term depletion of EWS-FLI1, a subset of sarcoma cells slowly proliferated and exhibited heterogeneous morphology (Figure 3D). The EWS-FLI1-depleted sarcoma cells expressed higher levels of osteogenic differentiation marker genes, as well as chondrogenic and adipogenic genes (Figures 3E and S3C). Moreover, long-term culture without EWS-FLI1 expression led to lipid production in a small subset of cells, as assessed by oil red O staining (Figure S3D).

SCOS#2 and SCOS#12 formed small-cell osteosarcomas in immunocompromised mice given Dox. These sarcoma cells had high proliferative activity based on Ki67 immunohistochemistry (Figure 3F). Consistent with in vitro findings that the growth of both SCOS#2 and SCOS#12 depends on EWS-FLI1 expression, the subcutaneous tumors stopped or retarded their growth after the withdrawal of Dox in vivo (Figures 3F and 3G). Of particular note, histological analysis revealed that the Dox-withdrawn tumors consisted of osteoid and mature bone tissue with a small number of blue cells (Figure 3F). These results indicated that depletion of EWS-FLI1 promoted osteogenic differentiation of
osteoosarcoma cells in vivo. Together, our results highlight the role of EWS-FLI1 expression on the suppression of terminal differentiation of osteosarcoma cells.

EWS-FLI1 Binds to the ETS Motif in EWS-FLI1-Induced Osteosarcoma Cells
To investigate how EWS-FLI1 suppresses the expression of osteogenic differentiation-related genes, we performed chromatin immunoprecipitation-sequencing (ChIP-seq) analysis for hemagglutinin (HA)-tagged EWS-FLI1 in SCOS#2 cells using anti-HA antibody. The analysis identified 2,562 sites for EWS-FLI1 binding in EWS-FLI1-expressing SCOS#2. A motif analysis with HOMER (hyper-geometric optimization of motif enrichment) revealed that these binding sites often contain the ETS binding motif (Figure 3H), suggesting that EWS-FLI1 binds to the genome through the C-terminal ETS binding domain of FLI1. Previous studies demonstrated that EWS-FLI1 binds DNA preferentially at GGAA repeats to activate transcription. Indeed, we confirmed that the GGAA repeat is the most representative motif of EWS-FLI1 binding in SK-N-MC, a human Ewing sarcoma cell line (Figure 3I) (Riggi et al., 2014). Notably, the GGAA repeat was not enriched in SCOS#2 according to de novo motif analysis for EWS-FLI1 binding (Figure 3I).

One target of EWS-FLI1 in human Ewing sarcoma, N001, has 15 GGAA repeats 50 kb upstream from its transcription start site (TSS) in mouse. ChIP-seq data revealed that EWS-FLI1 does not bind to these GGAA repeats in SCOS#2, which is consistent with the fact that N001 expression is not affected by EWS-FLI1 expression in SCOS#2 (data not shown). We found similar GGAA repeats upstream and downstream of Nks2-2, Ccnd1, and Dkk2, which are also known targets of EWS-FLI1 binding in human Ewing sarcomas. However, there was no clear enrichment of EWS-FLI1 binding in SCOS#2. Ultimately, we found that only four of 2,562 EWS-FLI1 binding sites in SCOS#2 contained more than ten GGAA repeats, highlighting the difference in EWS-FLI1 binding between human Ewing sarcomas and our EWS-FLI1-induced osteosarcoma cells.

To further assess whether EWS-FLI1 binding affects the expression of adjacent genes, we first identified 126 genes that possess EWS-FLI1 binding sites close to their TSS (≤5 kb) and compared the expression between Dox (EWS-FLI1) ON and Dox OFF cells. No obvious difference in the expression levels of these genes was detected (Figure S4A). Similarly, EWS-FLI1 binding was not enriched near the TSSs of the genes upregulated or downregulated by Dox exposure (517 and 588 genes, respectively; cutoff point at fold change >1.5; Figure S4B). In contrast, the genome-wide analysis of EWS-FLI1 binding revealed that EWS-FLI1 was preferentially recruited to the distal intergenic region (72.5% of total binding sites) (Figures S4C and S4D). Our results indicate that EWS-FLI1 binds to the genome via the ETS motif, but EWS-FLI1 binding at the proximal regulatory region does not have a substantial impact on altered gene expressions in EWS-FLI1-induced osteosarcoma cells.

Figure 3. Inhibition of Osteogenic Differentiation by EWS-FLI1 in Small-Cell Osteosarcoma Cells
(A) Gene ontology enrichment analysis showed that the extracellular region and matrix-related genes are upregulated 72 hr after Dox withdrawal in SCOS#2 cells. The upregulated genes were selected by cutoff point at fold change >1.5 and p <1.0 × 10^-4. The top five enriched clusters are highlighted.
(B) Scatterplot analysis revealed that a number of osteogenesis and chondrogenesis-related genes were upregulated 72 hr after Dox withdrawal in SCOS#2 cells.
(C) At 5 days after Dox withdrawal, sarcoma cells exhibited alkaline phosphatase activity. Scale bars, 50 μm (upper) and 200 μm (lower).
(D) At 38 days after Dox withdrawal, slow-growing heterogeneous cells were observed. Scale bars, 200 μm.
(E) At 38 days after Dox withdrawal, cells showed higher expression of osteogenic differentiation-related genes. mRNA expression levels were measured by qRT-PCR. Data are presented as means ± SD (three technical replicates). The expression level of Dox ON cells was set to 1. Sost, Fgf23, and Mepe were undetectable in Dox ON samples by qRT-PCR, therefore, the expression level of Dox OFF cells was set to 1 instead.
(F) H&E and alizarin red staining demonstrated that Dox withdrawal leads to a significant reduction of the small blue cell population and an increase of mature bone formation. Ki67 immunohistochemistry shows the active proliferation of sarcoma cells in Dox ON condition. Scale bars, 200 μm (upper) and 50 μm (lower).
(G) In vivo tumor formation assay using sarcoma cell line SCOS#2 (n = 7, independent tumor). Dox treatment was withdrawn at 3 weeks, and mice were sacrificed at 7 weeks.
(H) The ETS motif was enriched in EWS-FLI1 binding sites according to motif analysis with HOMER of SCOS#2.
(I) De novo motif analysis identified the GGAA repeat as the most frequent motif in SK-N-MC. This repeat was not found in SCOS#2.
tool to study the impact of genetic abnormalities beyond EWS-FLI1 expression on sarcoma development. We therefore tried to establish iPSCs from SCOS#2 and SCOS#12. After single-cell cloning of sarcoma cells, we introduced OCT3/4, SOX2, KLF4, and c-MYC into the sarcoma cells and obtained iPSC-like colonies under the absence of EWS-FLI1 expression. These colonies were similar to those in normal ESCs and control iPSCs (Figure S5). An ANOVA test was used for the global gene expression patterns of iPSC-like cells in two independent sarcoma iPSCs teratomas, five independent osteogenic regions in the control iPSC, and nine independent osteogenic regions in two independent ESC teratomas, p < 0.05; sarcoma iPSCs vs control ESCs, p < 0.01; control ESCs vs control iPSCs, p > 0.05.

The sarcoma-derived iPSC-like cells exhibited demethylation of both Nanog promoter and Oct3/4 distal enhancer (Figure 4C), implying that these cells underwent epigenetic reorganization to acquire pluripotency. The silencing of the four exogenous factors, which occurs in the late stage of cellular reprogramming, was observed in some iPSC-like clones (Figure S5C), suggesting that these cells were fully reprogrammed. Then, we performed array comparative genomic hybridization (array CGH) and found that the single-cell-derived sarcoma cells had extensive chromosomal abnormalities (Figure S5D). Notably, sarcoma-derived iPSC-like cells harbored some identical chromosomal aberrations (Figure S5D). Furthermore, exome analysis revealed hundreds of identical missense mutations between SCOS#2 and sarcoma-derived iPSC-like cells (Figure S5E and Table S2), affirming that these iPSC-like clones were derived from the parental sarcoma cell. A subset of the mutated genes was also mutated in human Ewing sarcomas and osteosarcomas by the COSMIC database (http://cancer.sanger.ac.uk/cosmic) (Table S3). These sarcoma-derived iPSC-like cells lacked the ability to contribute to adult chimeric mice by blastocyst injection (data not shown), presumably because of the extensive genetic abnormalities observed in the CGH analysis and exome analysis. However, sarcoma-derived iPSC-like cells formed teratomas consisting of cells differentiating into three different germ layers when they were inoculated into the subcutaneous tissue of immunocompromised mice (Figure 4D), indicating that they have pluripotency. These results affirm that we succeeded in generating iPSCs from EWS-FLI1-induced osteosarcoma cells.

**Figure 4. Establishment of Sarcoma-Derived iPSCs and Differentiation of Sarcoma iPSCs into Osteogenic Cells**

(A) iPSCs-like cells were established from sarcoma cells by introducing reprogramming transcription factors. Scale bars, 200 μm.

(B) qRT-PCR revealed that the expression levels of pluripotency-related genes in sarcoma-derived iPSC-like cells were equivalent to those of ESCs. Data are presented as means ± SD (three technical replicates). The expression level of ESCs was set to 1.

(C) Bisulfite sequencing analyses revealed that the Nanog promoter and the Oct3/4 distal enhancer region are demethylated in sarcoma-derived iPSC-like cells. White and black circles indicate non-methylated and methylated cytosine at CpG sites, respectively.

(D) Sarcoma iPSCs gave rise to teratomas consisting of ectodermal, mesodermal, and endodermal tissue in the subcutaneous tissue of immunocompromised mice. Scale bars, 50 μm.

(E) Schematic illustrations of in vitro osteogenic differentiation.

(F) qRT-PCR analysis of osteogenic differentiation-related genes. Wild-type ESCs (V6.5). EWS-FLI1-inducible ESCs (Rosa-M2rtTA/Rosa::tetO-EWS-FLI1), and two independent fibroblast-derived iPSCs with Rosa-M2rtTA/Rosa::tetO-EWS-FLI1 alleles were used as controls in the osteogenic differentiation experiments. Sarcoma-derived iPSCs and control ESCs/iPSCs on day 0 and day 17 during osteogenic differentiation were examined for the expression of osteogenic differentiation-related genes. The mean ± SD is shown (three technical replicates per n; n = 3 biological replicates). The mean expression level of ESCs on day 17 was set to 1.

(G) Alizarin red staining revealed extracellular calcium deposits stained in blight reddish orange (day 28 after the induction of osteogenic differentiation). Scale bars, 20 μm.

(H) Histological analysis of an osteogenic region with osteoid production in teratomas. Ki67 immunohistochemistry revealed that osteoid-producing cells derived from sarcoma iPSCs have higher proliferative activities than those derived from control ESCs/iPSCs. Scale bars, 50 μm.

(I) Ki67 positive ratio of osteogenic regions in teratomas derived from sarcoma iPSCs or control ESCs/iPSCs. The mean ± SD of six independent osteogenic regions in two independent sarcoma iPSCs teratomas, five independent osteogenic regions in the control iPSC teratomas, and nine independent osteogenic regions in two independent ESC teratomas are shown. The ANOVA test was used for the statistical analysis. Sarcoma iPSCs vs control iPSCs, p < 0.05; sarcoma iPSCs vs control ESCs, p < 0.01; control ESCs vs control iPSCs, p > 0.05.
Figure 5. EWS-FLI1 Induces Sarcomas from Induced Osteogenic Cells in Concert with Genetic Aberrations
(A) EWS-FLI1 expression does not promote the growth of undifferentiated pluripotent stem cells. The means ± SD are shown in each group (two technical replicates per n; n = 3 biological replicates).
(B) Schematic illustration of in vitro osteogenic differentiation and EWS-FLI1 induction. The induced osteogenic cells (17 days after the induction of osteogenic differentiation) were subsequently treated with/without Dox for 2 weeks.
(C) The sarcoma iPSC-derived osteogenic cells acquired robust proliferation with Dox treatment, whereas control ESCs/iPSCs (Rosa-M2rtTA/Rosa::tetO-EWS-FLI1)-derived osteogenic cells did not. Scale bars, 200 μm.

(legend continued on next page)
differentiation, in sarcoma-derived iPSCs, the induction of osteogenic genes downstream of Runx2 was impaired even in the absence of EWS-FLI1 expression (day 17) (Figure 4F). Upon the prolonged induction of osteogenic differentiation (day 28), a mineralized area, as assessed by alizarin red staining, was detected in all samples (Figure 4G). However, the mineralized area was larger in control ESCs/iPSCs than in sarcoma-derived iPSCs (Figure 4G). We also employed the in vitro differentiation method of sarcoma iPSCs to generate teratomas in immunocompromised mice. Both the sarcoma iPSCs and the control ESCs/iPSCs formed teratomas, which contained an osteogenic region in the absence of EWS-FLI1 expression (Figure 4H). The Ki67-positive ratio of sarcoma iPSC-derived osteogenic cells was significantly higher than that of control ESC/iPSC-derived osteogenic cells (p < 0.05 and p < 0.01, respectively) (Figure 4I). Collectively, sarcoma-derived iPSCs exhibit impaired osteogenic differentiation irrespective of EWS-FLI1 expression, suggesting that genetic and epigenetic alterations besides EWS-FLI1 fusion also inhibit osteogenic differentiation and maintain the proliferating progenitor state.

**EWS-FLI1 Expression Induced Rapid Sarcoma Development from Sarcoma iPSC-Derived Osteogenic Cells**

Finally, we tried to analyze the cooperative action between EWS-FLI1 expression and the impaired differentiation associated with genetic aberrations on sarcoma development. EWS-FLI1 expression in both sarcoma iPSCs and control ESCs/iPSCs (Rosa-M2rtTA/Rosa::tetO-EWS-FLI1) has no promoting effect on cell growth under undifferentiated culture conditions (Figure 5A). Next, we induced osteogenic differentiation of sarcoma iPSCs and control cells in vitro and then EWS-FLI1 expression (Figure 5B). At day 17 of the osteogenic differentiation protocol, osteogenic precursor cells derived from sarcoma iPSCs and control cells were treated with Dox (Figure 5B). Of note, only the sarcoma-derived osteogenic cells showed robust proliferation in vitro in response to Dox at day 31 (Figures 5C and 5D). Xenograft of these cells resulted in tumor development only in mice given Dox (Figure 5E). Histological analysis revealed that these xenograft tumors were sarcomas that consisted of small round blue cells (Figure 5F). The secondary sarcoma harbored shared genetic mutations with SCOS (Figure S5E and Table S2). Osteogenic cells derived from control ESCs/iPSCs did not exhibit obvious EWS-FLI1-dependent growth in vivo (data not shown), affirming that sarcoma development requires additional aberrations. Interestingly, these tumors often contained a carcinoma component, therefore they were regarded as carcinosarcomas (Figure S5F). Presumably, this component reflected the contamination of heterogeneous cell types after in vitro osteogenic differentiation of the sarcoma iPSCs. Together, these results suggest that the impaired differentiation potential associated with the sarcoma genome contributes to a rapid malignant transformation of osteogenic cells upon EWS-FLI1 expression.

**DISCUSSION**

Although the exact cell of origin of Ewing sarcoma remains to be determined, it is suggested that Ewing sarcomas may arise from MSCs, which reside in the bone marrow (Riggi et al., 2008; Tirode et al., 2007). In the present study, we introduced the EWS-FLI1 fusion gene to bone marrow stromal cells to establish an Ewing sarcoma mouse model (Castillero-Trejo et al., 2005; Riggi et al., 2005). We successfully generated EWS-FLI1-induced sarcomas that depended on EWS-FLI1 expression in terms of in vitro proliferation and in vivo tumor development. However, the developed tumors were small-cell osteosarcomas composed of small round blue cells with osteoid formation. Small-cell osteosarcoma is a rare subtype of osteosarcomas, accounting for 1%–1.5% of all osteosarcomas (Nakajima et al., 1997). Notably, small-cell osteosarcoma exhibits shared properties with Ewing sarcoma (Righi et al., 2015). Moreover, EWSRI rearrangement, which includes EWS-FLI1, has been identified in a subset of small-cell osteosarcomas (Dragoeescu et al., 2013; Hill et al., 2002; Noguera et al., 1990; Oshima et al., 2004). The results of the present study demonstrate that the EWS-FLI1 fusion gene could function as a driver oncogene in a particular type of osteosarcoma and suggest that our model could be a rodent model for EWS-FLI1-dependent osteosarcomas.

The inhibition of differentiation has been considered to play a role in many types of tumor development through maintenance of the proliferating progenitor cell state. Previous studies demonstrated that the knockdown of EWS-FLI1 in Ewing sarcoma cell lines results in osteogenic, adipogenic and chondrogenic differentiation (Tirode et al., 2007). Similarly, in the present study, we found that
EWS-FLI1-induced osteosarcomas exhibit robust osteogenic differentiation after the withdrawal of EWS-FLI1 expression, indicating that EWS-FLI1 expression inhibits osteogenic differentiation. Molecular mechanisms by which EWS-FLI1 expression blocks osteogenic differentiation have been proposed in previous studies. It was reported that EWS-FLI1 inhibits osteogenic differentiation in murine multipotent mesenchymal cells by binding to Runx2, an osteogenic transcription factor, and inhibiting its function (Li et al., 2010). Similarly, EWSR1 was shown to interact with SOX9, which is involved in chondrogenic differentiation in zebrafish (Merkes et al., 2015). However, we failed to detect a physical interaction between EWS-FLI1 and Runx2 or Sox9 in our osteosarcoma cells by immunoprecipitation (data not shown), suggesting that another mechanism may exist for the defective differentiation. Notably, Riggi et al. (2014) demonstrated that EWS-FLI1 expression causes the displacement of endogenous ETS transcription factors and p300 at the canonical ETS motifs in Ewing sarcoma cells. We found that EWS-FLI1 binds to the genome through the ETS motif in EWS-FLI1-dependent osteosarcoma cells. Given that the ETS family of transcription factors plays an important role in osteogenic differentiation as well as adipogenic and chondrogenic differentiation (Birsoy et al., 2011; Iwamoto et al., 2007; Raouf and Seth, 2000), the aberrantly occupied ETS motifs by EWS-FLI1 might inhibit ETS family-mediated differentiation, resulting in maintenance of the proliferating progenitor state.

The majority of Ewing sarcomas arise in adolescence. Considering the young age at onset, it is suggested that Ewing sarcoma harbors few genetic abnormalities besides the EWS-FLI1 fusion gene. Indeed, recent genome-wide sequencing analyses revealed a paucity of somatic abnormalities (Crompton et al., 2014; Tirole et al., 2014). However, consistent with a number of previous studies, we failed to induce sarcomas by the sole expression of EWS-FLI1 in a variety of cell types in vivo, providing additional evidence that EWS-FLI1 expression is not sufficient for sarcoma development. Thus, we established iPSCs from EWS-FLI1-induced osteosarcoma cells, thereby harboring the same genetic abnormalities as the parental osteosarcoma cells. Interestingly, upon the induction of osteogenic differentiation, EWS-FLI1 expression turned sarcoma iPSC-derived osteogenic cells into sarcoma cells, whereas the expression was not sufficient for the transformation of those from control ESCs/iPSCs.

It is noteworthy that sarcoma iPSCs showed an impairment of terminal osteogenic differentiation ability irrespective of EWS-FLI1 expression. Notably, we found that osteogenic lineage cells derived from sarcoma iPSCs exhibit higher proliferating activity compared with cells derived from control ESCs/iPSCs. Taken together, it is conceivable that the additive effect by both EWS-FLI1 expression and the defective differentiation properties of sarcoma iPSCs promotes sarcoma development by suppressing terminal differentiation and maintaining the proliferating progenitor state.

The causative aberration of the impaired differentiation properties of sarcoma iPSCs remains unclear. Recently, Lee et al. (2015) established iPSCs from patients with Li-Fraumeni syndrome and demonstrated that mutant p53 causes defective osteoblastic differentiation. However, we failed to detect the Trp53 mutation in our sarcoma-derived iPSCs (Table S2), implying an alternative mechanism impairing osteogenic differentiation. Intriguingly, we observed that sarcoma iPSC teratomas sometimes exhibited impaired terminal differentiation of other lineages, which is also consistent with the fact that they lack the potential to make chimeric mice (Figure S5G). It is likely that a summation of extensive genetic abnormalities and epigenetic alterations is associated with the impaired differentiation of sarcoma iPSCs into multiple lineages. Further analysis is needed to determine the aberrations required for the sarcoma development associated with EWS-FLI1 expression.

The fact that the in vitro induction of osteogenic differentiation leads to sarcoma development from sarcoma iPSCs in concert with EWS-FLI1 expression indicates that these sarcomas arise from osteogenic progenitor cells. However, it is important to note that the withdrawal of EWS-FLI1 in osteosarcoma cells resulted in increased expression of multiple genes involved in chondrogenic and adipogenic differentiation in addition to osteogenic differentiation-related genes. Together with previous findings on Ewing sarcoma, multipotent progenitors that have partial commitment to the osteogenic lineage in the bone marrow could be a cell of origin for EWS-FLI1-induced osteosarcomas. This notion is also supported by the fact that a subset of small-cell osteosarcomas exhibits both chondrogenic and osteogenic differentiation (Dragoescu et al., 2013; Nakajima et al., 1997).

In summary, we established an EWS-FLI1-dependent small-cell osteosarcoma model by introducing EWS-FLI1 in mouse bone marrow stromal cells. We revealed that the impaired differentiation associated with both EWS-FLI1 expression and sarcoma-associated genetic abnormalities plays a critical role in the development and maintenance of EWS-FLI1-induced osteosarcomas. We propose that targeting impaired terminal differentiation could be a possible therapeutic strategy for EWS-FLI1-induced sarcomas.

**EXPERIMENTAL PROCEDURES**

**In Vivo Experiment**
Rosa-M2rtTA/Rosa::tetO-EWS-FLI1 and Rosa-M2rtTA/Col1a1::tetO-EWS-FLI1 chimeric mice were generated with KH2 (Beard et al., 2006). Rosa-M2rtTA/Rosa::tetO-EWS-FLI1 mice and immunocompromised mice inoculated with sarcoma cells were treated with...
Dox-containing water at 2 mg/ml with 10 mg/ml sucrose. *Rosa-
M2rtTA/Col1a1::tetO-EWS-FLI1* mice were treated with lower concentrations of Dox (100 µg/ml to 2 mg/ml) because of early lethality. For the xenograft assay, a total of 3 × 10⁶ EWS-FLI1-dependent immortalized cells, EWS-FLI1-dependent sarcoma cells, or ESCs/iPSCs were transplanted to immunocompromised mice. All animal experiments were approved by the CiRA Animal Experiment Committee, and the care of the animals was in accordance with institutional guidelines.

**iPSC Induction and Maintenance**

iPSC induction was performed by utilizing retroviral vectors (pMX-hOCT3/4, pMX-hSOX2, pMX-hKLF4, and pMX-hc-MYC; Addgene). Reprogramming factor-inducing single-cell-derived sarcoma cells were cultured in ESC media supplemented with human recombinant leukemia inhibitory factor (LIF; Wako), 2-mercaptoethanol (Invitrogen), and 50 µg/ml L-ascorbic acid (Sigma), and the established iPSCs were maintained with ESC media supplemented with LIF, 1 µM PD0325901 (Stemgent), and 3 µM CHIR99021 (Stemgent).

**In Vitro Differentiation of ESC/iPSCs to Osteogenic Lineage**

We employed the in vitro osteogenic differentiation protocol as described by Kim et al. (2010) with slight modifications. Briefly, 5,000 ESCs or iPSCs were cultured in a 96-well plate (Nunclon Sphere, Thermo Scientific) with E8 differentiation media (Isocove’s modified Dulbecco’s medium, 15% FBS, penicillin/streptomycin, L-glutamine, L-ascorbic acid, transferrin, thioglycerol) for 2 days. On day 2, retinoic acid was added (final concentration, 10⁻⁶ M). On day 5, embryo body cultures were collected and transferred to a 24-well tissue culture dish, and cultured in osteogenic differentiation media (a minimal essential medium, 10% FBS, penicillin/streptomycin, L-glutamine, 2 mM triiodothyronine, ITS). The media were changed every other day. On day 17, RNA was extracted, and osteogenic gene expression of the induced osteogenic cells was confirmed by real-time quantitative RT-PCR. Alizarin red staining was performed on day 28.

**Array Comparative Genomic Hybridization**

Genomic DNA was extracted with PureLink Genomic DNA Mini Kit (Invitrogen). Array comparative genomic hybridization analysis was performed with SurePrint G3 Mouse Genome CGH Microarray Kit (Agilent) and analyzed with Agilent Genomic Workbench 7.0.

**Microarray Analysis**

200 ng of total RNA prepared with an RNeasy Mini Kit was subjected to cDNA synthesis with a WT Expression Kit (Ambion), and the resultant cDNA was fragmented and hybridized to a Mouse Gene 1.0 ST Array (Affymetrix). The data obtained were analyzed using GeneSpring GX software (version 13.0, Agilent Technologies).

**ChIP-Seq Analysis**

ChIP (formaldehyde-assisted isolation of regulatory elements) was performed as described previously (Arioka et al., 2012). Anti-HA antibody (Nacalai, HA124, 06340-54) was used for the ChIP-Seq analysis. Sequencing libraries were generated using a TruSeq ChIP Sample Prep Kit (Illumina). The libraries were sequenced to generate single-end 100-bp reads using Illumina MiSeq. We used the MACS (Zhang et al., 2008) version 1.4.2 peak finding algorithm to identify regions of ChIP-seq enrichment over background with a p value 1 × 10⁻³. Ngs.plot was used to analyze and visualize the mapped reads (Shen et al., 2014). The motif analysis was performed using HOMER software (Heinz et al., 2010).

**Exome Analysis**

Genomic DNA of SCOS#2-A1, sarcoma iPSC#2-A1, and sarcoma-iPSC#2-A1-derived secondary sarcoma was extracted with a PureLink Genomic DNA Mini Kit (Invitrogen). Whole-exome capture was done with SureSelect XT (Agilent Technologies). The exome libraries were then sequenced on a HiSeq2500 (Illumina).

**ACCESSION NUMBERS**

The accession number for the data reported in this article is GEO: GSE72898.

**SUPPLEMENTAL INFORMATION**

Supplemental Information includes Supplemental Experimental Procedures, five figures, and four tables and can be found with this article online at http://dx.doi.org/10.1016/j.stemcr.2016.02.009.

**AUTHOR CONTRIBUTIONS**

S.K. and Y.Y. proposed the research project, designed the experiments, performed the experiments, and wrote the manuscript. T.Y., S.K., and F.I. analyzed microarray, ChIP-seq, and exome sequencing data. A.H., K.W., T.O., H.A., and K.S. provided technical instruction. K.S., H.S., and T.Y. analyzed data.

**ACKNOWLEDGMENTS**

We are grateful to P. Karagiannis for critical reading of this manuscript, T. Ukai, M. Yagi, T. Sato, and K. Osugi for technical assistance. The authors were supported in part by P-DIRECT, a Grant-in-Aid from the Ministry of Education, Culture, Sports, Science, and Technology of Japan, the Ministry of Health, Labor, and Welfare of Japan, SICORP, the Takeda Science Foundation, and the Naito Foundation.
