A Calculable Model for a Cavity and an Atomic Beam

H. TAMURA

and
Graduate School of Natural Science and Technology
Kanazawa University

ABSTRACT

We consider a simple model for the physical system consists of a cavity and a beam of atoms which pass the cavity successively.

The Hamiltonian contains time-dependent (piecewise constant) term describing interaction between the cavity and the atom in the beam which is passing the cavity at the prescribed moment. We deal with the model in which the radiation field inside the cavity and each atoms of the beam is modeled by simple harmonic oscillators.

We calculate the time evolution of the density matrix of the system and the asymptotic behavior of the cavity, both in the Hamiltonian dynamics and the Markovian dynamics of Kossakowski-Lindblad-Davies type. We also discuss the entropies and evolution of the reduced density matrix for subsystems near the cavity.

This talk is based on the joint work with Prof. V.A. Zagrebnov. The detailed description of the subject will be given in the forth coming paper.[TZ]
1 The Model

Let $a, a^*$ be the annihilation and the creation operators living in the one mode Fock space $\mathcal{F}$:

\[
[a, a^*] = 1, \quad [a, a] = 0, \quad [a^*, a^*] = 0.
\]

\[\mathcal{F} = \mathcal{F}_{\text{fin}}\]

\[\mathcal{F}_{\text{fin}} = \text{algebraic span of } \{\Omega, a^*\Omega, \cdots, a^{*k}\Omega, \cdots\}.\]

Let $\mathcal{H}_n (n = 0, 1, \cdots, N)$ be copies of $\mathcal{F}$ for a arbitrary but finite $N \in \mathbb{N}$. On the Hilbert space tensor product

\[\mathcal{H} = \bigotimes_{n=0}^{N} \mathcal{H}_n,\]

we define the operators

\[
\begin{align*}
b_0 &= a \otimes 1 \otimes \cdots \otimes 1, & \quad b_0^* &= a^* \otimes 1 \otimes \cdots \otimes 1, \\
b_1 &= 1 \otimes a \otimes 1 \otimes \cdots \otimes 1, & \quad b_1^* &= 1 \otimes a^* \otimes 1 \otimes \cdots \otimes 1, \\
b_2 &= 1 \otimes 1 \otimes a \otimes 1 \otimes \cdots \otimes 1, & \quad b_2^* &= 1 \otimes 1 \otimes a^* \otimes 1 \otimes \cdots \otimes 1,
\end{align*}
\]

and so on. The operators $b_j, b_j^* \ (j = 0, 1, 2, \cdots, N)$ satisfy CCR

\[\begin{align*}
[b_i, b_j^*] &= \delta_{ij}, \\
[b_i, b_j] &= [b_i^*, b_j^*] = 0.
\end{align*}\]

Remark : We regard $\mathcal{H}_0$ as the state space for the photon inside the cavity and $\mathcal{H}_n (n = 1, 2, \cdots, N)$ for internal states of atoms. So, $b_0^*, b_0$ are creation and annihilation operators of photon and $b_j^*, b_j$ are raising and lowering operator of the level of the $j$-th atom.

Remark : We consider the case $N < \infty$, for simplicity.

Let $H_n$ be the self-adjoint Hamiltonian in $\mathcal{H}$ defined by

\[
H_n = Eb_0^*b_0 + \epsilon \sum_{k=1}^{N} b_k^*b_k + \eta b_0^*b_n + \eta b_n^*b_0, \quad (n = 1, 2, \cdots, N)
\]

where $E > 0$ is the photon energy, $\epsilon > 0$ the energy level spacing of the atoms and $\eta > 0$ the interaction between the photon and atoms. We assume that $\eta$ is small enough so that $H_n$ is bounded below. (We understand that all operators like $H_n$ are taken to be closed.) We regard that $H_n$ is the Hamiltonian during the time interval $[(n - 1)\tau, n\tau)$ when the $n$-th atom is passing inside the cavity.
2 Hamiltonian Dynamics

In this section, we consider the time evolution of the system governed by the time dependent (piecewise constant) Hamiltonian:

\[ H(t) = \sum_{n=1}^{N} \chi_{[(n-1)\tau, n\tau)}(t)H_n. \]

The commutation relations

\[
[H_n, b_0] = -Eb_0 - \eta b_n, \quad [H_n, b_j] = -\epsilon b_j - \delta_{jn}\eta b_0, \\
[H_n, b_0^*] = Eb_0^* + \eta b_n^*, \quad [H_n, b_j^*] = \epsilon b_j^* + \delta_{jn}\eta b_0^*
\]

hold for \( j = 1, \ldots, N \) and yield the following lemma.

**Lemma 2.0.1** For \( j = 0, 1, 2, \ldots, N \) and \( n = 1, 2, \ldots, N \),

\[
e^{-i\tau H_n}b_je^{i\tau H_n} = \sum_{k=0}^{N} (U_n)_{jk}b_k, \quad e^{-i\tau H_n}b_j^*e^{i\tau H_n} = \sum_{k=0}^{N} \overline{(U_n)_{jk}}b_k^*, \\
e^{i\tau H_n}b_je^{-i\tau H_n} = \sum_{k=0}^{N} (U_n^*)_{jk}b_k, \quad e^{i\tau H_n}b_j^*e^{-i\tau H_n} = \sum_{k=0}^{N} \overline{(U_n^*)_{jk}}b_k^*
\]

hold. Here \( U_n \) and \( V_n \) are \((N+1) \times (N+1)\) matrices given by \( U_n = e^{i\tau\epsilon}V_n \) and

\[
(V_n)_{jk} = \begin{cases} 
gz \delta_{k0} + gw \delta_{kn} & (j = 0) \\
-g\overline{w} \delta_{k0} + g\overline{z} \delta_{kn} & (j = n) \\
\delta_{jk} & \text{(otherwise)}
\end{cases}
\]

with

\[
g = e^{i\tau(E-\epsilon)/2}, \quad w = \frac{2i\eta}{\sqrt{(E-\epsilon)^2 + 4\eta^2}} \sin \tau \sqrt{\frac{(E-\epsilon)^2}{4} + \eta^2}, \\
z = \cos \tau \sqrt{\frac{(E-\epsilon)^2}{4} + \eta^2} + \frac{i(E-\epsilon)}{\sqrt{(E-\epsilon)^2 + 4\eta^2}} \sin \tau \sqrt{\frac{(E-\epsilon)^2}{4} + \eta^2}.
\]
Note that $|z|^2 + |w|^2 = 1$ and that
\[
\begin{pmatrix} z & w \\ -\bar{w} & \bar{z} \end{pmatrix}
\]
is a unitary matrix. And so are $V_n$'s and $U_n$'s.

e.g.
\[
U_1 = e^{i\tau\epsilon}V_1 = e^{i\tau\epsilon}
\begin{pmatrix} gz & gw & 0 & 0 & 0 & \cdots \\ -g\bar{w} & g\bar{z} & 0 & 0 & 0 & \cdots \\ 0 & 0 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 1 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 1 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\end{pmatrix}
\]
\[
U_2 = e^{i\tau\epsilon}V_2 = e^{i\tau\epsilon}
\begin{pmatrix} gz & 0 & gw & 0 & 0 & \cdots \\ 0 & 1 & 0 & 0 & 0 & \cdots \\ -g\bar{w} & 0 & g\bar{z} & 0 & 0 & \cdots \\ 0 & 0 & 0 & 1 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 1 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\end{pmatrix}
\]

2.1 Time evolution of Product states

For $y \in \mathbb{C}$,
\[
w(y) = e^{i(ga + ya^*)}
\]
denotes the Weyl operator over $\mathcal{F}$. We consider the Weyl algebra $\mathcal{A}(\mathcal{F})$ over $\mathcal{F}$ generated by $\{w(y)\}_{y \in \mathbb{C}}$ and the algebra $\mathcal{A}(\mathcal{H})$ over $\mathcal{H}$ which is generated by
\[
W(\zeta) = \bigotimes_{k=0}^{N} w(\zeta_k), \quad (\zeta = \{\zeta_k\}_{k=0}^{N}). \tag{2.1}
\]

Using sesquilinear form notation
\[
\langle \zeta, b \rangle = \sum_{j=0}^{N} \bar{\zeta}_j b_j, \quad \langle b, \zeta \rangle = \sum_{j=0}^{N} \zeta_j b_j^*.
\]
$W(\zeta)$ can be written as

$$W(\zeta) = \exp[i(\langle \zeta, b \rangle + \langle b, \zeta \rangle)].$$

Let $\rho_k$ be a normalized self-adjoint non-negative trace class operator on $\mathcal{F}$ for $k = 0, 1, 2, \ldots, N$. It can be regarded as a state on $\mathcal{A}(\mathcal{F})$. We use the notation

$$C_k(y) = \text{Tr}_\mathcal{F}[w(y)\rho_k].$$

Similarly, we consider the operator

$$\rho = \bigotimes_{k=0}^{N} \rho_k$$

as a state on $\mathcal{A}(\mathcal{H})$:

$$\omega_{\rho}(W(\zeta)) = \text{Tr}_\mathcal{F}[W(\zeta)\rho] = \prod_{k=0}^{N} C_k(\zeta_k).$$

Let us consider the time evolution of $\rho$ by $H(t)$ $(0 \leq t \leq N\tau)$:

$$\rho(N\tau) := e^{-i\tau H_N} \cdots e^{-i\tau H_1} \rho e^{i\tau H_1} \cdots e^{i\tau H_N}.$$

Lemma 2.1.1

$$\omega_{\rho(N\tau)}(W(\zeta)) = \omega_{\rho}(W(U_1 \cdots U_N \zeta)) = \prod_{k=0}^{N} C_k((U_1 \cdots U_N \zeta)_k)$$

holds, where

$$(U_1 \cdots U_N \zeta)_0 = e^{iN\tau}(g(z)^N \zeta_0 + \sum_{j=1}^{N} g^j w(gz)^{j-1} \zeta_j)$$

and

$$(U_1 \cdots U_N \zeta)_k = e^{iN\tau}( - g\bar{w}(gz)^{N-k} \zeta_0 + g\bar{z} \zeta_k - \sum_{j=k+1}^{N} g^2 |w|^2(gz)^{j-k-1} \zeta_j)$$

for $k > 0$. 

179
2.2 The product Gibbs state

For the product Gibbs density matrix $\rho = \bigotimes_{k=0}^{N} \rho_{k}$ with
\[ \rho_0 = e^{-\beta_0 a^* a}/Z(\beta_0), \quad \rho_j = e^{-\beta a^* a}/Z(\beta) \ (j = 1, \ldots, N), \quad (2.2) \]
where $\beta, \beta_0 > 0$ and $Z(\beta) = (1 - e^{-\beta})^{-1}$, we have

**Lemma 2.2.1** The state corresponding to the density matrix (2.4) satisfies
\[ \omega_{\rho}(W(\zeta)) = \text{Tr}_{\mathcal{H}}[W(\zeta)\rho] = \exp\left[-\frac{|\zeta_0|^2}{2} \left(\frac{1 + e^{-\beta_0}}{1 - e^{-\beta_0}} - \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right) - \frac{\langle\zeta,\zeta\rangle}{2} \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right] \]
and
\[ S(\rho) = -\text{Tr}[\rho \log \rho] = Ns(\beta) + s(\beta_0), \]
where $s(\beta) := \beta(e^\beta - 1)^{-1} - \log(1 - e^{-\beta})$.

The time evolution of the density matrix $\rho(N\tau) = e^{-i\tau H_N}e^{-i\tau H_{N-1}}\cdots e^{-i\tau H_1}\rho e^{i\tau H_1}\cdots e^{i\tau H_N}$ satisfies the following properties:

**Lemma 2.2.2**
\[ \omega_{\rho(N\tau)}(W(\zeta)) = \omega_{\rho}(W(U_1\cdots U_N\zeta)) = \exp\left[-\frac{|(U_1\cdots U_N\zeta)_0|^2}{2} \left(\frac{1 + e^{-\beta_0}}{1 - e^{-\beta_0}} - \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right) - \frac{\langle\zeta,\zeta\rangle}{2} \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right], \]
and
\[ S(\rho(N\tau)) = Ns(\beta) + s(\beta_0) = S(\rho). \]

The relative entropy of $\rho(N\tau)$ w.r.t. $\rho$ is:

**Lemma 2.2.3**
\[ S(\rho(N\tau)|\rho) = -\text{Tr}[\rho(N\tau)(\log \rho(N\tau) - \log \rho)] = -\text{Tr}[\rho(\log \rho - \log \rho(-N\tau))] \]
\[ = -\frac{(\beta_0 - \beta)(e^{\beta_0} - e^{\beta})}{(e^{\beta_0} - 1)(e^{\beta} - 1)}(1 - |\zeta|^{2N}). \]

**Remark** The relative entropy is non-positive generally. In this case, it decreases monotonically as $N \to \infty$ and converges to the limit:
\[ \lim_{N \to \infty} S(\rho(N\tau)|\rho) = -\frac{(\beta_0 - \beta)(e^{\beta_0} - e^{\beta})}{(e^{\beta_0} - 1)(e^{\beta} - 1)}. \]
2.3 Subsystems

In this section, we divide the system into 2 subsystems. At time $t = k\tau$, the
objects are ordered as follows:

the first atom, \( \cdots \), the $k$-th atom, the cavity, the $k + 1$-th atom, \( \cdots \), the $N$-th atom.

We regard the cavity and the $n$ atoms ahead the cavity as the subsystem:

$$\mathcal{H} = \mathcal{H}_s \otimes \mathcal{H}_r,$$

where

$$\mathcal{H}_s = \mathcal{H}_0 \otimes \bigotimes_{j=1}^{n} \mathcal{H}_{k-j+1}, \quad \mathcal{H}_r = \bigotimes_{j=1}^{k-n} \mathcal{H}_j \otimes \bigotimes_{j=n+1}^{N} \mathcal{H}_j$$

We want to re-number the atoms in the subsystem:

For take

$$\theta = \begin{pmatrix} \theta_0 \\ \theta_1 \\ \vdots \\ \theta_n \end{pmatrix} \in \mathbb{C}^{n+1},$$

$$\zeta_\theta^{(k)} = \begin{pmatrix} \theta_0 & \leftarrow 0 \text{-th} \\ 0 & \leftarrow 1 \text{-th} \\ \vdots \\ \theta_{n-1} \leftarrow k - n \text{-th} \\ \theta_n \leftarrow k - n + 1 \text{-th} \\ \theta_{n+1} \leftarrow k - n + 2 \text{-th} \end{pmatrix} \in \mathbb{C}^{N+1}$$
to get
\[ \theta_0 b_0^* + \bar{\theta}_0 b_0 + \sum_{j=1}^{n}(\theta_j b_{k-j+1}^* + \bar{\theta}_j b_{k-j+1}) = \sum_{j=0}^{N}(\zeta_{\theta,j}^{(k)} b_j^* + \bar{\zeta}_{\theta,j}^{(k)} b_j). \]

And consider the Weil operator on \( \mathscr{H}_s \)
\[ W_s(\theta) = \exp\[i(\theta_0 b_0^* + \bar{\theta}_0 b_0 + \sum_{j=1}^{n}(\theta_j b_{k-j+1}^* + \bar{\theta}_j b_{k-j+1}))\] \[= \exp\[i(\theta_0 \tilde{b}_0^* + \bar{\theta}_0 \tilde{b}_0 + \sum_{j=1}^{n}(\theta_j \tilde{b}_j^* + \bar{\theta}_j \tilde{b}_j)\], \]

where, \( \tilde{b}_0 = b_0, \tilde{b}_j = b_{k-j+1} \). (We used abused notations: e.g., \( b_0 \) is not an operator in \( \mathscr{H}_s \) but in \( \mathscr{H} \), while \( \tilde{b}_0 \) in \( \mathscr{H}_s \), etc.)

For the density matrix \( \rho \), let \( \rho_s \) be the reduced density matrix of the sub-system i.e.,
\[ \rho_s = \text{Tr}_{\mathscr{H}_r} \rho. \] (2.3)

Then, we get
\[ \omega_{\rho_s}(W_s(\theta)) = \omega_{\rho}(W(\zeta_{\theta})). \]

Now let us consider time evolution. The time evoluted density \( \rho(k\tau) \) of the initial Gibbs state
\[ \rho = \exp\[-\beta_0 b_0^* b_0 - \beta \sum_{j=1}^{N} b_j^* b_j]/(Z(\beta_0)Z(\beta)^N), \] (2.4)

has the reduced density matrix given by

\textbf{Lemma 2.3.1}
\[ \omega_{\rho(k\tau)_s}(W_s(\theta)) = \omega_{\rho(k\tau)}(W(\zeta_{\theta})) \]
\[= \exp\[-\frac{|(U_1 \cdots U_k \zeta_{\theta})_0|^2}{2}(1 + e^{-\beta_0} - \frac{1}{1 - e^{-\beta}} - \frac{\langle \theta, \theta \rangle}{2} \frac{1 + e^{-\beta}}{1 - e^{-\beta}})\], \]

Now consider the limit \( k \to \infty \) (\( N \to \infty \)) with \( n \) fixed. We get
Proposition 2.3.2 $\rho(k\tau)_s$ converge to $\rho^{(\beta)}$ and

$$\lim_{k \to \infty} S(\rho(k\tau)_s) = S(\rho^{(\beta)}),$$

where

$$\rho^{(\beta)} = \exp \left[ -\beta b_0^* b_0 - \beta \sum_{j=1}^{n} b_{N-j+1}^* b_{N-j+1} \right] / Z(\beta)^{n+1}.$$ 

Remark The local entropy decreases or increases according to $\beta > \beta_0$ or $\beta < \beta_0$, respectively.

2.4 A scaling limit for product states

Here, we mention an asymptotic behavior of the state of the cavity under the influence of the beam where the state for the atoms is product of general type.

We assume that

1. $\rho_1 = \rho_2 = \cdots = \rho_N$;
2. $\text{Tr}[a\rho_1] = \text{Tr}[a^2\rho_1] = \text{Tr}[a^*\rho_1] = \text{Tr}[a^{*2}\rho_1] = 0$;
3. $\text{Tr}[(a^*a)^2\rho_1] < \infty$.

Proposition 2.4.1 Under the limit $\tau \to 0$ and $N \to \infty$ subject to $\tau^2 N \to \infty$ and $\tau^3 N \to 0$ (e.g., $\tau = O(N^{-0.4})$),

$$\lim_{\rho(N\tau)_s} \omega(w(\theta)) = \lim_{\rho(N\tau)} \omega(W(\zeta_\theta)) = e^{-\text{Tr}[\rho(a^{*}a+a^{*}a)]|\theta|^2/2}$$

holds for $\theta \in \mathbb{C}^{0+1}$.

3 Markovian Evolution

We consider here the evolution of the system under the Kossakowski-Lindblad-Davies equation, which yields a behavior the system in a large reservoir:

$$\partial_t \rho(t) = L_\sigma(t)(\rho(t)), \quad \rho = \rho(t)|_{t=0} \in \mathcal{C}_1(\mathcal{H}),$$

where

$$L_\sigma(t)(\rho(t)) := -i[H(t), \rho(t)] + \sigma_- b_0 \rho(t) b_0^* - \frac{\sigma_-}{2} \{b_0^* b_0, \rho(t)\}$$

$$+ \sigma_+ b_0^* \rho(t) b_0 - \frac{\sigma_+}{2} \{b_0 b_0^*, \rho(t)\}.$$
To satisfy the complete positivity-preserving the parameters of non-Hamiltonian part of dynamics must satisfy inequality $\sigma_{\mp} \geq 0$. We also impose condition $\sigma_{\pm} \leq \sigma_{-}$ for the boundedness of expectations in the state, see [NVZ].

We introduce the family \{$T_{t,t'}^\sigma\}_{0 \leq t' \leq t}$ of trace-preserving and complete-positive evolution mappings:

$$T_{t,0}^\sigma : \rho \mapsto \rho_{\sigma}(t) = T_{t,0}^\sigma(\rho(0)) \quad \text{with} \quad T_{t,0}^\sigma = T_{t,t'}^\sigma T_{t',0}^\sigma, \quad (0 \leq t' \leq t).$$

As in the Hamiltonian evolution, we consider tuned repeated interactions, when the Hamiltonian part of dynamics is piecewise constant. Then for $t \in [(k-1)\tau, k\tau)$, the generator has the form:

$$L_{\sigma,k}(\rho(t)) := -i[H_{k}, \rho(t)] + \sigma_{-} b_{0} \rho(t) b_{0}^* - \frac{\sigma_{-}}{2}\{b_{0}^* b_{0}, \rho(t)\}$$

$$+ \sigma_{+} b_{0}^* \rho(t) b_{0} - \frac{\sigma_{+}}{2}\{b_{0} b_{0}^*, \rho(t)\} \quad (k \geq 1).$$

The solution of the corresponding Cauchy problem

$$\partial_{t}\rho(t) = L_{\sigma}(t)(\rho(t)), \quad \rho(t)|_{t=0} = \rho_{0} \otimes \bigotimes_{k=1}^{N} \rho_{k},$$

has a form:

$$\rho(N\tau) = T_{N\tau,0}^\sigma(\rho(0)) = e^{\tau L_{\sigma,N}} ... e^{\tau L_{\sigma,2}}e^{\tau L_{\sigma,1}}(\rho(0)).$$

Let us use the notation:

$$T_{k}^\sigma := T_{k\tau,(k-1)\tau}^\sigma = e^{\tau L_{\sigma,k}}.$$ 

And we consider evolution of the Weyl operators, which is dual to the evolution of states

$$\text{Tr}\mathcal{W}[T_{N\tau,0}^\sigma(\rho)W(\zeta)] = \text{Tr}\mathcal{W}[\rho T_{N\tau,0}^{\sigma\ast}(W(\zeta))].$$

Note that

$$T_{N\tau,0}^\sigma = e^{\tau L_{\sigma,N}} ... e^{\tau L_{\sigma,2}}e^{\tau L_{\sigma,1}}$$

and its dual evolution

$$T_{N\tau,0}^{\sigma\ast} = e^{\tau L_{\sigma,1\ast}}e^{\tau L_{\sigma,2\ast}} ... e^{\tau L_{\sigma,N\ast}}.$$ 

(3.7)
3.1 Evolution of Open System

First we establish a formula for the one-step mappings in (3.7) of the Weyl operators.

**Lemma 3.1.1** Let $k, l = 0, 1, 2, \ldots, N$ and $n = 1, 2, \ldots, N$. Let vector $\zeta = \{\zeta_k\}_{k=0}^N \in \mathbb{C}^{N+1}$ be as in (2.1). Then we obtain

\[ T_n^\sigma(W(\zeta)) := e^{itL_{\sigma,n}^*}W(\zeta) = \Omega_t^{\sigma,n}(\zeta)W(U_n^\sigma(t)\bar{\zeta}) , \quad (3.8) \]

where

\[ \Omega_t^{\sigma,n}(\zeta) = \exp\left[-\frac{1}{4}\frac{\sigma_+ + \sigma_-}{\sigma_+ - \sigma_-} \left(\langle U_n^\sigma(t)\zeta, U_n^\sigma(t)\zeta\rangle - \langle \zeta, \zeta \rangle\right)\right] , \quad (3.9) \]

\[ U_n^\sigma(t) = \exp\left[it \left(Y_n - i \frac{\sigma_+ - \sigma_-}{2} P_0\right)\right] \quad \text{and} \quad (P_0)_{kl} = \delta_{k0}\delta_{l0}. \quad (3.10) \]

**Remark** The main difference between the mapping for $\sigma_\mp = 0$ and (3.8), (3.10) is that the energy parameter (Lemma 2.0.1) has the shift:

\[ E \rightarrow E_\sigma := E - i \frac{\sigma_+ - \sigma_-}{2} . \]

Note that $\text{Im}(E_\sigma) > 0$, if $\sigma_+ < \sigma_-$. 

**Corollary 3.1.2**

\[ T_{N\tau,0}^\sigma(W(\zeta)) = \exp\left[-\frac{\sigma_+ + \sigma_-}{4(\sigma_+ - \sigma_-)} \left(\langle U_\tau^\sigma(\tau)\ldots U_1^\sigma(\tau)\zeta, U_\tau^\sigma(\tau)\ldots U_1^\sigma(\tau)\zeta\rangle - \langle \zeta, \zeta \rangle\right)\right] \]

\[ \times W(U_\tau^\sigma(\tau)\ldots U_N^\sigma(\tau)\zeta). \]

Combining the above Corollary and Lemma, we get the following theorem.

**Theorem 3.1.3** Let $\rho$ be the Gibbs density matrix (2.2). Then, we get

\[ \omega_{T_{N\tau,0}^\sigma,\rho}(W(\zeta)) = \exp\left[-\frac{1}{4}\langle \zeta, X^\sigma(N\tau)\zeta \rangle\right] , \]

where $X^\sigma(N\tau)$ is the $(N+1) \times (N+1)$ matrix given by

\[ X^\sigma(N\tau) = U_N^\sigma(\tau)^*\ldots U_1^\sigma(\tau)^* \left[\left(\frac{\sigma_+ + \sigma_-}{\sigma_+ - \sigma_-} + \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right)I + \left(\frac{1 + e^{-\beta_0}}{1 - e^{-\beta_0}} - \frac{1 + e^{-\beta}}{1 - e^{-\beta}}\right)P_0\right] \]

\[ \times U_1^\sigma(\tau)\ldots U_N^\sigma(\tau) - \frac{\sigma_+ + \sigma_-}{\sigma_+ - \sigma_-} I. \]
3.2 Limit of reduced density for the cavity

Hereafter, we use the notations: 

\[ U_n^\sigma(t) = e^{it\epsilon}V_n^\sigma(t) \]

\[
(V_n^\sigma(t))_{jk} = \begin{cases} 
  g^\sigma(t)z^\sigma(t) \delta_{k0} + g^\sigma(t)w^\sigma(t) \delta_{kn} & (j = 0) \\
  g^\sigma(t)w^\sigma(t) \delta_{k0} + g^\sigma(t)z^\sigma(-t) \delta_{kn} & (j = n) \\
  \delta_{jk} & \text{(otherwise)}
\end{cases}
\]

with

\[
g^\sigma(t) = e^{it(E_\sigma-\epsilon)/2}, \quad w^\sigma(t) = \frac{2i\eta}{\sqrt{(E_\sigma-\epsilon)^2 + 4\eta^2}} \sin t \sqrt{\frac{(E_\sigma-\epsilon)^2}{4} + \eta^2}.
\]

\[
z^\sigma(t) = \cos t \sqrt{\frac{(E_\sigma-\epsilon)^2}{4} + \eta^2} + \frac{i(E_\sigma-\epsilon)}{\sqrt{(E_\sigma-\epsilon)^2 + 4\eta^2}} \sin t \sqrt{\frac{(E_\sigma-\epsilon)^2}{4} + \eta^2}.
\]

(3.11)

(3.12)

Note the relation \( z^\sigma(t)z^\sigma(-t) - w^\sigma(t)^2 = 1 \) holds, but \( z^\sigma(-t) \neq \overline{z^\sigma(t)} \) for \( \sigma^+ \neq \sigma^- \).

We consider the system with initial product state

\[
\rho := \bigotimes_{k=0}^{N} \rho_k \quad \text{with} \quad \rho_1 = \rho_2 = \cdots = \rho_N, \quad (3.13)
\]

where \( \rho_0, \rho_1 \) are density matrices on \( \mathcal{F} \). We assume that \( \rho_1 \) is gauge invariant. For fixed \( \rho_1 \), we define one step evolution of the cavity state \( \rho_0 \) by

\[
T(\rho_0) = (T_{\tau,0}^\sigma \rho)_0, \quad (3.14)
\]

where \( \rho \) is (3.13) and the subscript \( (\_)_0 \) in the righthand side represents the reduced density corresponding to the subsystem consists of the cavity only. The application of \( T \) can be expressed explicitly by the use of the expectation of the Weyl operator:

\[
\omega_{T(\rho_0)}(\hat{w}(\theta)) = \exp \left[ -\frac{\left| \theta \right|^2}{4} \frac{\sigma_- + \sigma_+}{\sigma_- - \sigma_+} (1 - |g^\sigma(\tau)z^\sigma(\tau)|^2 - |g^\sigma(\tau)w^\sigma(\tau)|^2) \right]
\]

\[
\times \omega_{\rho_0}(\hat{w}(e^{it\epsilon}g^\sigma(\tau)z^\sigma(\tau)\theta)\omega_{\rho_1}(\hat{w}(e^{it\epsilon}g^\sigma(\tau)w^\sigma(\tau)\theta)) \omega_{\rho_0}(\hat{w}(e^{it\epsilon}g^\sigma(\tau)z^\sigma(\tau)\theta)). \quad (3.15)
\]

Then we get:
Proposition 3.2.1 Suppose that

\[
E(\theta) := \prod_{k=0}^{\infty} \omega_{\rho_{1}}(\hat{w}(e^{i(k+1)\tau_{\epsilon}}g^{\sigma}(\tau)^{(k+1)}z^{\sigma}(\tau)^{k}w^{\sigma}(\tau)\theta))
\]

is convergent and continuous for all \(\theta \in \mathbb{C}\). Then there is a unique state \(\rho_{*}\) on \(\mathcal{A}(\mathcal{F})\) which satisfies

(i) \(T(\rho_{*}) = \rho_{*}\), \hspace{1cm} (3.16)

(ii) \(\forall \rho_{0} \in \mathfrak{C}_{1}(\mathcal{F}) : \lim_{k \to \infty} T^{k}(\rho_{0}) = \rho_{*}\), \hspace{1cm} (3.17)

(iii) \(\lim_{N \to \infty} (T_{N\tau,0}^{\sigma}\rho)_{s} = (T_{n\tau,0}\rho_{(*)})_{s}\), \hspace{1cm} (3.18)

where in the third item, \(\rho_{(*)}\) is (3.13) with \(\rho_{0} = \rho_{*}\) and the subscript \(s\) stands for the reduced density to the subsystem consists of the cavity and the \(n\) atoms near the cavity, see (2.3).

Moreover \(\rho_{*}\) have the expectation

\[
\omega_{\rho_{*}}(\hat{w}(\theta)) = \exp \left[ -\frac{|\theta|^{2}}{4} \frac{\sigma_{-} + \sigma_{+}}{\sigma_{-} - \sigma_{+}} \left( 1 - \frac{|g^{\sigma}(\tau)w^{\sigma}(\tau)|^{2}}{1 - |g^{\sigma}(\tau)z^{\sigma}(\tau)|^{2}} \right) \right] E(\theta). \hspace{1cm} (3.19)
\]

4 Summary

As a simple mathematical model for atomic beam passing through a cavity, we considered a system consists of harmonic oscillators.

We have studied the Hamiltonian evolution of the system by calculating the expectation values of Weyl operators, explicitly. For Gibbs initial states, we consider a relaxation phenomena of the sub-system arround the cavity. For initial product states, we saw the convergence to the Gibbsian density matrix in a certain scaling limit.

We also studied the Markovian evolution of the model. We gave a formula for the dual evolution of the Weyl operators, explicitly. For a certain initial product states, we gave the asymptotic behavior of the states for subsystems around the cavity.

The detailed presentation of the subject and their proofs will be given in [TZ].
