Kyoto University
Singularities of Tangent Surfaces and Generalised Frontals

Goo Ishikawa
Department of Mathematics, Hokkaido University, Japan.

1 Introduction

In this survey article we give expositions about the resent researches for the generic singularities which appear on tangent surfaces in various geometric frameworks. Actually we give the review of the recent paper [19] with the results appeared in [15][16][17][18].

Given a curve in Euclidean 3-space $E^3 = R^3$, the embedded tangent lines to the curve draw a surface in $R^3$, which is called the tangent surface (or tangent developable) to the curve.

It is known that the tangent surfaces (tangent developables) are developable surfaces. Developable surfaces which are locally isometric to the plane keep on interesting many mathematicians, for instance, Monge (1764), Euler (1772), Cayley (1845), Lebesgue (1899). See [23] for details. Therefore the tangent surfaces are regarded as generalised solutions (with singularities) of the Monge-Ampère equation

$$\frac{\partial^2 z}{\partial x^2} \frac{\partial^2 z}{\partial y^2} - \left(\frac{\partial^2 z}{\partial x\partial y}\right)^2 = 0$$

on spacial surfaces $z = z(x, y)$. This property is related to “projective duality”: The projective dual of a tangent surface collapse to a curve (the dual curve). See [11].

Let $\gamma : R \rightarrow R^3$ be an immersed curve. Then the tangent surface has the natural parametization

$$\text{Tan}(\gamma) : R^2 \rightarrow R^3, \quad \text{Tan}(\gamma)(t, s) := \gamma(t) + s\gamma'(t).$$

The tangent surface necessarily has singularities at least along $\gamma$, “the edge of regression".
Example 1.1 Let $\gamma : \mathbb{R} \rightarrow \mathbb{R}^3$, $\gamma(t) = (t, t^2, t^3)$. Then the tangent surface $\text{Tan}(\gamma) : \mathbb{R}^2 \rightarrow \mathbb{R}^3$ is given by $\text{Tan}(\gamma) = \gamma(t) + s\gamma'(t) = (t + s, t^2 + 2st, t^3 + 3st^2)$. For the Jacobi matrix we have

$$J_F = \begin{pmatrix} 1 & 1 \\ 2t + 2s & 2t \\ 3t^2 + 6st & 3t^2 \end{pmatrix} \sim \begin{pmatrix} 0 & 1 \\ 2s & 2t \\ 6st & 3t^2 \end{pmatrix}$$

and we have rank $J_F < 2$ if and only if $s = 0$. Take the transversal $\{x_1 = 0\}$, then, $s = -t$, and we have $x_2 = -t^2, x_3 = -2t^3$, the planar cusp.

It is known that the tangent surface to a generic curve $\gamma : \mathbb{R} \rightarrow \mathbb{R}^3$ in $\mathbb{R}^3$ has singularities only along $\gamma$ and is locally diffeomorphic to the cuspidal edge or to the folded umbrella (also called, the cuspidal cross cap), as is found by Cayley and Cleave (1980). Cuspidal edge singularities appear along ordinary points where $\gamma', \gamma'', \gamma'''$ are linearly independent, while the folded umbrellas appear at isolated points of zero torsion where $\gamma', \gamma'', \gamma'''$ are linearly dependent but $\gamma', \gamma'', \gamma'''$ are linearly independent.

The diffeomorphism equivalence is given by the commutative diagram:

$$
\begin{array}{ccc}
(R^2, (t_0, s_0)) & \xrightarrow{F} & (R^3, F(t_0, s_0)) \\
\circlearrowright & & \circlearrowright \\
(R^2, (t_1, s_1)) & \xrightarrow{G} & (R^3, G(t_1, s_1)) \\
\end{array}
$$
More degenerate singularities of tangent surfaces are classified by Mond, Arnold, Scherbak... See [11].

In a higher dimensional space $\mathbb{R}^m, m \geq 4$, for an immersed curve $\gamma : \mathbb{R} \to \mathbb{R}^m$, we define the tangent surface $\text{Tan}(\gamma) : \mathbb{R}^2 \to \mathbb{R}^m$ by $\text{Tan}(\gamma)(t, s) := \gamma(t) + s\gamma'(t)$. Then we have generically that $\gamma', \gamma'', \gamma'''$ are linearly independent and $\text{Tan}(\gamma)$ is locally diffeomorphic to the (embedded) cuspidal edge in $\mathbb{R}^m$. See [14].

![Embedded cuspidal edge](image)

A (not necessarily immersed) $C^\infty$ curve $\gamma : \mathbb{R} \to \mathbb{R}^m$ is called directed if there exists a frame $u : \mathbb{R} \to \mathbb{R}^m, u(t) \neq 0$, such that

$$\gamma'(t) \in \langle u(t) \rangle_R, \quad t \in \mathbb{R}.$$ 

It is the projection of a $C^\infty$ curve $\tilde{\gamma} : \mathbb{R} \to \mathbb{PTR}^m$ satisfying

$$\gamma'(t) \in \tilde{\gamma}(t), \quad (t \in \mathbb{R}),$$

where

$$\mathbb{PTR}^m = \{(x, \ell) | x \in \mathbb{R}^m, \ell \subset T_x\mathbb{R}^m, \dim(\ell) = 1\}$$

is the manifold consisting of all tangential lines.

![Directed curve](image)

$A$ directed curve $t \mapsto (t^2, t^3, t^4)$ in $\mathbb{R}^3$.

Then the tangent surface $\text{Tan}(\gamma) : \mathbb{R}^2 \to \mathbb{R}^m$ of a directed curve $\gamma$ is defined by

$$\text{Tan}(\gamma)(t, s) := \gamma(t) + s u(t)$$

The right equivalence class of $\text{Tan}(\gamma)$ is independent of the choice of frame $u$.

![Tangent surface](image)

Tangent surface $\text{Tan}(\gamma)$ of the directed curve.
Then we have

**Theorem 1.2** ([14]) The singularities of the tangent surface \( \text{Tan}(\gamma) \) for a generic directed curve \( \gamma : \mathbb{R} \to \mathbb{R}^m \) on a neighbourhood of the curve are only the cuspidal edge, the folded umbrella, and swallowtail if \( m = 3 \), and the embedded cuspidal edge and the open swallowtail if \( m \geq 4 \).

![Swallowtail in \( \mathbb{R}^3 \), Open Swallowtail in \( \mathbb{R}^4 \).](image)

The notion of tangent surfaces ruled by "tangent lines" to directed curves is naturally generalised in various ways:
- For a curve in a projective space, regard tangent projective lines as "tangent lines".
- For a curve in a Riemannian manifold, regard tangent geodesics as "tangent lines".
- For a null curve of a semi (pseudo)-Riemannian manifold, regard tangent lines by null geodesics.
- For a horizontal curve of a sub-Riemannian manifold, regard tangent lines by abnormal geodesics.

## 2 \( A_n \)-geometry

We would like to show generalisations (or specialisations) to the cases with additional geometric structures. In the paper [18], we have given a series of classification results of singularities of tangent surfaces in \( D_n \)-geometry, i.e. the geometry associated with the group \( O(n, n) \) preserving. In this occasion we will give a series of classification results of singularities of tangent surfaces in \( A_n \)-geometry, i.e. the geometry associated to the group \( \text{PGL}(n+1, \mathbb{R}) \).

Let \( V = \mathbb{R}^{n+1} \) be the vector space of dimension \( n + 1 \) and consider a flag in \( V \) of the following type (a complete flag):

\[
V_1 \subset V_2 \subset V_3 \subset \cdots \subset V_n \subset V, \quad \dim(V_i) = i.
\]

The set of such flags form a manifold of dimension \( \frac{n(n+1)}{2} \).

A one-parameter family of flags (a curve on the flag manifold)

\[
V_1(t) \subset V_2(t) \subset V_3(t) \subset \cdots \subset V_n(t) \subset V
\]

is called **admissible** if the infinitesimal movement of \( V_1(t) \) at \( t_0 \) belongs to \( V_2(t_0) \), the infinitesimal movement of \( V_2(t) \) at \( t_0 \) belongs to \( V_3(t_0) \) and so on, for any \( t_0 \).

A curve in the projective space \( P(V) = P(V^{n+1}) \) arises an admissible curve if we regard its osculating planes: the curve itself is given by \( V_1(t) \), the tangent line is given by \( V_2(t) \), the osculating plane is given by \( V_3(t) \) and so on.

We can define a distribution (a differential system) on the flag manifold such that a curve on the flag manifold is admissible if and only if the curve is an integral curve to that distribution. The distribution is one of Cartan's canonical distributions defined from simple Lie algebras, the central objects for the theory by Noboru Tanaka after E. Cartan.
Let $n = 2$. Let $V_1(t) \subset V_2(t) \subset V = \mathbb{R}^3$ be an admissible curve. For each $t_0$, planes $V_2$ satisfying $V_1(t_0) \subset V_2 \subset V$ form the tangent line to the curve $\{V_1(t)\}$ at $t = t_0$ in $P(V) = \mathbb{P}^2$. Similarly lines $V_1$ satisfying $V_1 \subset V_2(t_0)$ form the tangent line to the dual curve $\{V_2(t)\}$ at $t = t_0$ in $\text{Gr}(2, V) = P(V^*) = \mathbb{P}^2$, the dual projective plane. For a generic admissible curve, we have the duality on "tangent maps":

Let $n = 3$. Let $V_1(t) \subset V_2(t) \subset V_3(t) \subset V = \mathbb{R}^4$ be an admissible curve. It induces a curve in $P^3 = P(\mathbb{R}^4)$, a curve in $\text{Gr}(2, \mathbb{R}^4)$ and a curve in $P^3* = \text{Gr}(3, \mathbb{R}^4)$ naturally. Then we have the following duality on their "tangent surfaces", which are ruled by tangent lines defined naturally by the flags:

<table>

For a generic admissible curve

$V_1(t) \subset V_2(t) \subset V_3(t) \subset \cdots \subset V_n(t) \subset V,$

we have the classification of singularities of tangent surfaces:

**Theorem 2.1** ($A_n, n \geq 4$) The classification list consists of $n + 1$ cases for curves in Grassmannians:

The cuspidal edge (resp. open swallowtail, open Mond surface, open folded umbrella) is defined as a diffeomorphism class of the tangent surface-germ to a curve of type $(1, 2, 3, \cdots)$ (resp. $(2, 3, 4, 5, \cdots), (1, 3, 4, 5, \cdots), (1, 2, 4, 5, \cdots)$) in an affine space. Their normal forms are given as follows:

\[
\begin{align*}
\text{CE} & : (\mathbb{R}^2, 0) \rightarrow (\mathbb{R}^m, 0), \ m \geq 3, \\
& \quad (u, t) \mapsto (u, t^2 - 2ut, 2t^3 - 3ut^2, 0, \ldots, 0).
\end{align*}
\]

\[
\begin{align*}
\text{OSW} & : (\mathbb{R}^2, 0) \rightarrow (\mathbb{R}^m, 0), \ m \geq 4, \\
& \quad (u, t) \mapsto (u, t^3 - 3ut, t^4 - 2ut^2, 3t^5 - 5ut^3, 0, \ldots, 0).
\end{align*}
\]

\[
\begin{align*}
\text{OM} & : (\mathbb{R}^2, 0) \rightarrow (\mathbb{R}^m, 0), \ m \geq 4, \\
& \quad (u, t) \mapsto (u, 2t^3 - 3ut^2, 3t^4 - 4ut^3, 4t^5 - 5ut^4, 0, \ldots, 0).
\end{align*}
\]

\[
\begin{align*}
\text{OFU} & : (\mathbb{R}^2, 0) \rightarrow (\mathbb{R}^m, 0), \ m \geq 4, \\
& \quad (u, t) \mapsto (u, t^2 - 2ut, 3t^4 - 4ut^3, 4t^5 - 5ut^4, 0, \ldots, 0).
\end{align*}
\]

The “stability” of the classification lists of singularities for flags of type $A_n$ when $n \rightarrow \infty$ (from $n \geq 4$) is observed.

### 3 Affine connection and tangent surface

Now let us consider the case of directed curves in a Riemannian manifold, or more generally, the case of directed curves in a manifold with any affine connection, which is not necessarily projectively flat. For any directed curve, we have the well-defined tangent geodesic to each point of the curve. If we regard it as the “tangent line”, then we have the well-defined tangent surface for the directed curve.

\[
\begin{align*}
\text{CE} & \quad \text{OSW} & \quad \text{OM} & \quad \text{OFU}
\end{align*}
\]

**Theorem 3.1** ([19]) *For any affine connection on a manifold of dimension $m \geq 3$, the singularities of the tangent surface to a generic directed curve on a neighbourhood of the curve are only the cuspidal edge, the folded umbrella, and swallowtail if $m = 3$, and the embedded cuspidal edge and the open swallowtail if $m \geq 4$.***

**Theorem 3.2** ([19])

*Let $\nabla$ be any torsion-free affine connection on a manifold $M$. Let $\gamma : \mathbb{R} \rightarrow M$ be a $C^\infty$ curve.*
(1) Let \( \dim(M) = 3 \). If \((\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), (\nabla^3 \gamma)(t_0)\) are linearly independent at \( t = t_0 \in \mathbb{R} \), then the tangent surface \( \text{Tan}(\gamma) \) is locally diffeomorphic to the cuspidal edge at \((t_0, 0) \in \mathbb{R}^2 \). If \((\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), (\nabla^3 \gamma)(t_0)\) are linearly dependent, and \((\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), (\nabla^4 \gamma)(t_0)\) are linearly independent, then the tangent surface \( \text{Tan}(\gamma) \) is locally diffeomorphic to the folded umbrella at \((t_0, 0) \in \mathbb{R}^2 \). If \((\nabla \gamma)(t_0) = 0\) and \((\nabla^2 \gamma)(t_0), (\nabla^3 \gamma)(t_0), (\nabla^4 \gamma)(t_0)\) are linearly independent, then the tangent surface \( \text{Tan}(\gamma) \) is locally diffeomorphic to the swallowtail at \((t_0, 0) \in \mathbb{R}^2 \).

(2) Let \( \dim(M) \geq 4 \). If \((\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), (\nabla^3 \gamma)(t_0)\) are linearly independent at \( t = t_0 \in \mathbb{R} \), then the tangent surface \( \text{Tan}(\gamma) \) is locally diffeomorphic to the embedded cuspidal edge at \((t_0, 0) \in \mathbb{R}^2 \). If \((\nabla \gamma)(t_0) = 0\) and

\[
(\nabla^2 \gamma)(t_0), (\nabla^3 \gamma)(t_0), (\nabla^4 \gamma)(t_0), (\nabla^5 \gamma)(t_0)
\]

are linearly independent at \( t = t_0 \in \mathbb{R} \), then the tangent surface \( \text{Tan}(\gamma) \) is locally diffeomorphic to the open swallowtail at \((t_0, 0) \in \mathbb{R}^2 \).

4 Degeneracy type of a curve

Let \( \gamma : \mathbb{R} \to M \) be a \( C^\infty \) curve and \( t_0 \in I \). Define

\[
a_1 := \inf \left\{ k \mid k \geq 1, (\nabla^k \gamma)(t_0) \neq 0 \right\}.
\]

Note that \( \gamma \) is an immersion at \( t_0 \) if and only if \( a_1 = 1 \). If \( a_1 < \infty \), then define

\[
a_2 := \inf \left\{ k \mid \text{rank } (\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), \ldots, (\nabla^k \gamma)(t_0) = 2 \right\}.
\]

We have \( 1 \leq a_1 < a_2 \). If \( a_i < \infty, 1 \leq i < \ell \leq m \), then define \( a_\ell \) inductively by

\[
a_\ell := \inf \left\{ k \mid \text{rank } (\nabla \gamma)(t_0), (\nabla^2 \gamma)(t_0), \ldots, (\nabla^k \gamma)(t_0) = \ell \right\}.
\]

If \( a_m < \infty \), then we call the strictly increasing sequence \((a_1, a_2, \ldots, a_m)\) of natural numbers the type of \( \gamma \) at \( t_0 \).

In the generic cases, types for curves uniquely determine the local diffeomorphism classes of tangent surfaces.

5 Generalised frontals

**Definition 5.1** Let \( n \leq m = \dim(M) \). A \( C^\infty \) map-germ \( f : (\mathbb{R}^n, p) \to M \) is called a frontal, in a generalised sense, if there exists a \( C^\infty \) frame \( V_1, V_2, \ldots, V_n : (\mathbb{R}^n, p) \to TM \) along \( f \) and a \( C^\infty \) function-germ \( \sigma : (\mathbb{R}^n, p) \to \mathbb{R} \) such that

\[
(\frac{\partial f}{\partial t_1} \wedge \frac{\partial f}{\partial t_2} \wedge \cdots \wedge \frac{\partial f}{\partial t_n})(t) = \sigma(t)(V_1 \wedge V_2 \wedge \cdots \wedge V_n)(t),
\]

as germs of \( n \)-vector fields \((\mathbb{R}^n, p) \to \wedge^n TM\) over \( f \). Here \( t_1, t_2, \ldots, t_n \) are coordinates on \((\mathbb{R}^n, p)\).

For \( n = 1 \), a frontal was called a directed curve.
A frame of swallowtail in $\mathbb{R}^3$.

The singular locus (non-immersive locus) $S(f)$ of $f$ coincides with the zero locus $\{\sigma = 0\}$ of $\sigma$. We call $\sigma$ a **signed area density function** or briefly an *s-function* of the frontal $f$ associated with the frame. We say that frontal $f : (\mathbb{R}^n, p) \to M$ has a **non-degenerate** singular point at $p$ if the signed area density function $\sigma$ of $f$ satisfies that $\sigma(p) = 0$ and $d\sigma(p) \neq 0$. The condition is independent of the choice of $V_1, V_2, \ldots, V_n$ and $\sigma$. If $f$ has a non-degenerate singular point at $p$, then $f$ is of corank 1 such that the singular locus $S(f) \subset (\mathbb{R}^n, p)$ is a regular hypersurface. The above notions are generalisations of those introduced in the case $n = 2, \dim(M) = 3$ by Kokubu, Rossman, Saji, Umehara, Yamada (2005) and Fujimori, Saji, Umehara, Yamada (2008).

The following is one the keys to show the above theorems:

**Proposition 5.2** Let $\gamma : \mathbb{R} \to M$ be a $C^\infty$ curve, $t_0 \in \mathbb{R}$, and $k \geq 1$. Suppose that $(\nabla^i \gamma)(t_0) = 0$ for $0 \leq i < k$ and $(\nabla^k \gamma)(t_0), (\nabla^{k+1} \gamma)(t_0)$ are linearly independent. Then the germ of tangent surface $Tan(\gamma)$ is a frontal with non-degenerate singular point at $(t_0, 0)$ and with the singular locus $S(\nabla - Tan(\gamma)) = \{s = 0\}$. Moreover $Tan(\gamma)$ is diffeomorphic to an “opening” of a plane-to-plane map-germ $(\mathbb{R}^2, 0) \to (\mathbb{R}^2, 0)$ of Thom-Boardman type $\Sigma^{1^k, 0}$.

We also need the characterisation of swallowtails (resp. the characterisation of cuspidal cross caps (folded umbrella)) found by Kokubu, Rossman, Saji, Umehara, Yamada (2005) (resp. Fujimori, Saji, Umehara, Yamada (2008)).

We briefly give the coordinate-free characterisations of cuspidal edge and cuspidal cross cap by Fujimori, Saji, Umehara, Yamada (2008).

Let $f : (\mathbb{R}^2, p) \to M^3$ be a frontal with a non-degenerate singular point $p$ with a frame $V_1, V_2$. Take an annihilator $L : (\mathbb{R}^2, p) \to T^* M \setminus \zeta$ of $V_1, V_2$, a kernel field $\eta : (\mathbb{R}^2, p) \to TM$ of the differential $f_*$, and a parametrisation $c : (\mathbb{R}, t_0) \to (\mathbb{R}^2, p)$ of the singular locus $S(f)$. Suppose $V_2(p) \notin f_*(T_p \mathbb{R}^2)$. Then define

$$\psi(t) = \langle L(c(t), (\nabla_0^i V_2)(c(t))) \rangle.$$

In terms of the function $\psi$, the characterisations are given:

- $f$ is diffeomorphic to the cuspidal edge if and only if $\psi(t_0) \neq 0$.
- $f$ is diffeomorphic to the cuspidal cross cap (or the folded umbrella) if and only if $\psi(t_0) = 0, \psi'(t_0) \neq 0$.

## 6 Geometric structures on spaces

Now we recall the classification of simple Lie algebras over the complex numbers by Dynkin diagrams [4]:

![Dynkin diagram](image-url)
Dynkin diagrams of simple Lie algebras $\mathbb{C}$

We also recall the relations on several Dynkin diagrams with few vertices:

We recall the generic singularities of “tangent maps” of planar fronts in $A_2$-geometry (planar projective geometry):
Then the classification of singularities of tangent surfaces looks like an "opening" of $A_2$ theory. However, we need to construct explicit geometric model and perform detailed calculation to realise the exact list of the classification.

7 Distribution and its integral curves

The notion of "tangent surfaces" is generalised in various ways. For an integral curve in a sub-Riemannian manifold, we regard tangent abnormal geodesics as tangent lines.

Let $M$ be a $C^\infty$ manifold and $\mathcal{D} \subset TM$ a subbundle of the tangent bundle $TM$. Often $\mathcal{D}$ is called a distribution or a differential system on $M$.

**Definition 7.1** A $C^\infty$ curve $\gamma : \mathbb{R} \to M$ is called $\mathcal{D}$-integral if

$$\gamma'(t) \in \mathcal{D} \quad (t \in \mathbb{R}).$$

Moreover $\gamma : \mathbb{R} \to M$ is called $\mathcal{D}$-directed if there exists a $C^\infty$ mapping $u : \mathbb{R} \to \mathcal{D}$ such that the following diagram commutes:

$$\begin{array}{ccc}
u & \circ & \pi \\
\gamma & \searrow & M \\
\downarrow & & \\
\circ & & \searrow \pi
\end{array}$$

and that

$$\begin{cases}
u(t) \neq 0, \\
\gamma'(t) \in \langle u(t) \rangle_{\mathbb{R}}, \ t \in \mathbb{R}.
\end{cases}$$

Let $(M, \mathcal{D}, g)$ be a sub-Riemannian manifold. Here $\mathcal{D} \subset TM$ is a (completely non-integrable) distribution, and $g$ is a Riemannian metric on $\mathcal{D}$. Regarding the problem on length minimising on $\mathcal{D}$-integral curves $\gamma : [a, b] \to M$,

$$\ell(\gamma) = \int^{b}_{a} \sqrt{g_{\gamma(t)}(\gamma'(t), \gamma'(t))} dt,$$

we have two kinds of geodesics (extremals), normal geodesics and abnormal geodesics. Note that in Riemannian geometry, where $\mathcal{D} = TM$, all geodesics are normal. Moreover it is known that abnormal geodesics are defined only by the distribution $\mathcal{D}$.

8 $G_2$-Cartan distribution

Let $M$ be a 5-dimensional manifold and $\mathcal{D} \subset TM$ a distribution of rank 2. Then $\mathcal{D}$ is called a Cartan distribution if it has growth $(2, 3, 5)$, namely, if $\text{rank}(\mathcal{D}^{(2)}) = 3$ and $\text{rank}(\mathcal{D}^{(3)}) = 5$, where, we define in terms of Lie bracket, $\mathcal{D}^{(2)} = \mathcal{D} + [\mathcal{D}, \mathcal{D}]$ and $\mathcal{D}^{(3)} = \mathcal{D}^2 + [\mathcal{D}, \mathcal{D}^2]$. It is known that, for any point $x$ of $M$ and for any direction $\ell \subset \mathcal{D}_x$, there exists an abnormal geodesic, which is unique up to parametrisations, through $x$ with the given direction $\ell$. 

![Diagram of $G_2$-Cartan distribution](image-url)
Then, for a given $\mathcal{D}$-directed curve $\gamma$, we define abnormal tangent surface of $\gamma$, which is ruled by abnormal geodesics through points $\gamma(t)$ with the directions $u(t)$.

On $\mathbb{R}^5$ with coordinates $(\lambda, \nu, \mu, \tau, \sigma)$, define the distribution $\mathcal{D} \subset T\mathbb{R}^6$ generated by the pair of vector fields

$$
\eta_1 = \frac{\partial}{\partial \lambda} + \nu \frac{\partial}{\partial \mu} - (\lambda \nu - \mu) \frac{\partial}{\partial \tau} + \nu^2 \frac{\partial}{\partial \sigma},
$$

$$
\eta_2 = \frac{\partial}{\partial \nu} - \lambda \frac{\partial}{\partial \mu} + \lambda^2 \frac{\partial}{\partial \tau} - (\lambda \nu + \mu) \frac{\partial}{\partial \sigma}.
$$

Then $\mathcal{D}$ is a Cartan distribution and it has maximal symmetry of dimension 14, maximal among all Cartan distributions, which is of type $G_2$, one of simple Lie algebras. The distribution $\mathcal{D} \subset T\mathbb{R}^6$ is also defined by $\{\beta_1 = 0, \beta_2 = 0, \beta_3 = 0\}$ where

$$
\beta_1 := -\nu \lambda + \lambda \nu + d \mu = 0,
$$

$$
\beta_2 := (\lambda \nu - \mu) d \lambda - \lambda^2 d \nu + d \tau = 0,
$$

$$
\beta_3 := -\nu^2 d \lambda + (\lambda \nu + \mu) d \nu + d \sigma = 0.
$$

**Theorem 8.1** ([16], $G_2$)

For a generic $G_2$-Cartan directed curve $\gamma : \mathbb{R} \to \mathbb{R}^5$, the tangent surfaces at any point $t_0 \in \mathbb{R}$ is classified, up to local diffeomorphisms, into embedded cuspidal edge, open Mond surface, and generic open folded pleat.

-cuspidal edge
-open Mond
-GPFP $(2, 3, 5, \ldots)$

Note that the work is closely related to the rolling ball problem [1][3][2].

## 9 Null curves in a semi-Riemannian manifold

Let $(M, g)$ be a semi-Riemannian manifold with an indefinite metric $g$. Denote by $\mathcal{C} \subset TM$ the null cone field associated with the indefinite metric $g$, i.e. $\mathcal{C}$ is the set of null vectors,

$$
\mathcal{C} = \{u \in TM \mid u \in T_x M, g_x(u, u) = 0\}.
$$

**Definition 9.1** A $C^\infty$ curve $\gamma : \mathbb{R} \to M$ is called a null curve if

$$
\gamma'(t) \in \mathcal{C} \quad (t \in \mathbb{R}).
$$

Moreover $\gamma : \mathbb{R} \to M$ is called null-directed if there exists a $C^\infty$ mapping $u : \mathbb{R} \to \mathcal{C}$ such that

$$
u : \mathbb{R} \to \mathcal{C},
$$

and that

$$
\left\{\begin{array}{l}
u(t) \neq 0,
\gamma'(t) \in \langle \nu(t) \rangle_M,
t \in \mathbb{R}.
\end{array}\right.
$$
Define the “null” tangent surface of a null-directed curve $\gamma$ as the ruled surface by null geodesics through points $\gamma(t)$ with the directions $u(t)$.

Let $M = \mathbb{R}^{p,q}$ be the $\mathbb{R}^{p+q}$ with the metric of signature $(p, q)$,

$$(x|y) = -x_{1}y_{1} - \cdots - x_{p}y_{p} + x_{p+1}y_{p+1} + \cdots + x_{p+q}y_{p+q}.$$  

Then we have the generic classification of singularities of tangent surfaces by null geodesics in $\mathbb{R}^{1,2}$:

**Theorem 9.2** ($B_{2} = C_{2}$, [6][15])

The singularities of tangent surface $\text{Tan}(\gamma)$ for a generic null directed curve $\gamma : \mathbb{R} \to \mathbb{R}^{1,2}$ are cuspidal edges, swallowtails and Scherbak surfaces.

Now consider a curve in $\mathbb{R}^{2,2}$. The $D_{3}$-evolute of the curve is defined by the envelope of the 1-parameter of normals along the curve.

The tangent surface is embedded as (the closure of) a stratum in $D^{3}$-evolute. The Kazaryan’s bi-umbrella appears as a transversal section of the evolute.

Then we have the classification result on singularities of tangent surfaces:

**Theorem 9.3** ($D_{3}$, [18]) The singularities of tangent surface $\text{Tan}(\gamma)$ for a generic null directed curve $\gamma : \mathbb{R} \to \mathbb{R}^{2,2}$ are embedded cuspidal edges and open swallowtails.
For generic singularities of tangent surfaces by null geodesics in $\mathbb{R}^{2,3}$, we have:

**Theorem 9.4** The singularities of tangent surface $\text{Tan}(\gamma)$ for a generic null directed curve $\gamma : \mathbb{R} \to \mathbb{R}^{2,3}$ are embedded cuspidal edges, open swallowtails, open Mond surfaces and unfurled folded umbrellas.

The **unfurled folded umbrella** is the singularities of the tangent surface of a curve of type $(1, 2, 4, 6, 7)$.

For the generic singularities of tangent surfaces by null geodesics in $\mathbb{R}^{3,3}$, we have:

**Theorem 9.5** The singularities of tangent surface $\text{Tan}(\gamma)$ for a generic null directed curve $\gamma : \mathbb{R} \to \mathbb{R}^{3,3}$ (the projection of a generic “Engel integral” curve) are embedded cuspidal edges, open swallowtails and open Mond surfaces.

### 10 Type of a curve and singularity of tangent surface

Several types for curves uniquely determine the local diffeomorphism classes of tangent surfaces.

<table>
<thead>
<tr>
<th>Singularity of tangent surface</th>
<th>Type of curve</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mond surface</td>
<td>$(1, 3, 4)$</td>
</tr>
<tr>
<td>open Mond surface</td>
<td>$(1, 3, 4, 5, \ldots)$</td>
</tr>
<tr>
<td>unfurled Mond surface</td>
<td>$(1, 3, 4, 6, \ldots)$</td>
</tr>
<tr>
<td>Scherbak surface</td>
<td>$(1, 3, 5)$</td>
</tr>
<tr>
<td>open Scherbak surface</td>
<td>$(1, 3, 5, 7, 8, \ldots)$</td>
</tr>
<tr>
<td>unfurled folded umbrella</td>
<td>$(1, 2, 4, 6, 7, \ldots)$</td>
</tr>
</tbody>
</table>
These characterisations are confirmed in the flat case so far. To confirm these characterisation of singularities in non-flat case is an interesting problem.
