Nardilysin is involved in autoimmune arthritis via the regulation of tumour necrosis factor alpha secretion

Takayuki Fujii,1 Eiichiro Nishi,2,3 Hiromu Ito,1 Hiroyuki Yoshitomi,4 Moritoshi Furu,5 Namiko Okabe,6 Mikiko Ohno,2 Kiyoto Nishi,2 Yusuke Morita,2 Yugo Morita,1 Masayuki Azukizawa,1 Akinori Okahata,1 Takuya Tomizawa,1 Takeshi Kimura,2 Shuichi Matsuda1

ABSTRACT

Objective Tumour necrosis factor alpha (TNF-α) plays an important role in rheumatoid arthritis (RA). TNF-α is synthesised as a membrane-anchored precursor and is fully activated by a disintegrin and metalloproteinase 17 (ADAM17)-mediated ectodomain shedding. Nardilysin (NRDC) facilitates ectodomain shedding via activation of ADAM17. This study was undertaken to elucidate the role of NRDC in RA.

Methods NRDC-deficient (Nrdc−/−) mice and macrophage-specific NRDC-deficient (Nrdcα/α) mice were examined in murine RA models, collagen antibody-induced arthritis (CAIA) and K/BxN serum transfer arthritis (K/BxN STA). We evaluated the effect of gene deletion or silencing of Nrdc on ectodomain shedding of TNF-α in macrophages or monocytes. NRDC concentration in synovial fluid from patients with RA and osteoarthritis (OA) were measured. We also examined whether local gene silencing of Nrdc ameliorated CAIA.

Results CAIA and K/BxN STA were significantly attenuated in Nrdc−/− mice and Nrdcα/α mice. Gene deletion or silencing of Nrdc in macrophages or THP-1 cells resulted in the reduction of TNF-α shedding. The level of NRDC is higher in synovial fluid from RA patients compared with that from OA patients. Intra-articular injection of anti-Nrdcs small interfering RNA ameliorated CAIA.

Conclusion These data indicate that nardilysin plays crucial roles in the pathogenesis of autoimmune arthritis and could be a new therapeutic target for RA treatment.

INTRODUCTION

Rheumatoid arthritis (RA) is a chronic inflammatory disease that causes joint inflammation and destruction affecting 0.5%–1.0% of the population.1 Anti-tumour necrosis factor alpha (TNF-α) biologic agents have led to a revolutionary improvement in the management of RA patients, indicating that this inflammatory cytokine plays a key role in RA pathogenesis. The importance of TNF-α has been also demonstrated in murine models of RA; for example, human TNF-α transgenic mice develop arthritis,2 TNF-α is produced in synovial tissues of murine experimental models of RA,3 murine experimental arthritis is attenuated in TNF-α-deficient mice1 and neutralisation of TNF-α ameliorates murine collagen-induced arthritis.4 TNF-α is produced mostly by macrophages in RA synovial tissues5 and, alone or in combination with other cytokines or chemokines, recruits inflammatory cells such as B cells, T cells and neutrophils, and induces production of cytokines, chemokines, matrix metalloproteinases or receptor activator of nuclear factor κB ligand, resulting in joint inflammation and bone resorption.6–11

One of the earliest subclinical features of RA is a breakdown of self-tolerance. Autoantibodies such as rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA) are found in
the patients’ serum long before arthritis occurs. While the autoantigens have not been fully identified, autoantibodies may contribute to the pathogenesis of RA via immunocomplex (IC) formation and deposition in synovial tissues. The importance of autoantibodies has been demonstrated in mouse autoantibody-induced arthritis (AAIA) models of RA, such as collagen antibody-induced arthritis (CAIA) and K/BxN serum transfer arthritis (K/BxN STA). Antibodies against intra-articular antigens, type II collagen in CAIA and glucose-6-phosphoisomerase in K/BxN STA are arthrogenic in mice. TNF-α has been demonstrated to be important in both models: anti-TNF-α antibody attenuates CAIA, while TNF-α-deficient mice are resistant to K/BxN STA.

Importantly, TNF-α is synthesized as a membrane-anchored precursor and is fully activated by a disintegrin and metalloprotease 17 (ADAM17)-mediated ectodomain shedding, indicating that ADAM17 is an attractive alternative target for treatment of RA. However, the multiple disease phenotypes of ADAM17-deficient patients and mice have raised concerns about the potential adverse effects of anti-ADAM17 therapy. We have previously shown that direct binding to ADAM17. NRDC is a zinc peptidase of the M16 family that selectively cleaves dibasic sites. We identified NRDC on the cell surface as a specific binding partner of heparin-binding epidermal growth factor (EGF)-like growth factor (HB-EGF) and demonstrated that NRDC enhances ectodomain shedding of HB-EGF. Our subsequent studies revealed that NRDC enhances ectodomain shedding of not only HB-EGF but also a wide range of other membrane proteins including TNF-α, neuregulin 1 and amyloid precursor protein.

NRDC is a zinc peptidase of the M16 family that selectively cleaves dibasic sites. We identified NRDC on the cell surface as a specific binding partner of heparin-binding epidermal growth factor (EGF)-like growth factor (HB-EGF) and demonstrated that NRDC enhances ectodomain shedding of HB-EGF. Our subsequent studies revealed that NRDC enhances ectodomain shedding of not only HB-EGF but also a wide range of other membrane proteins including TNF-α, neuregulin 1 and amyloid precursor protein. We have also demonstrated that NRDC-induced ectodomain shedding plays critical roles in myelination, gastric cancer and Alzheimer’s disease.

We demonstrate here that NRDC-deficient (Nrdc<sup>−/−</sup>) mice and macrophage-specific NRDC-deficient (Nrc<sup>−/−</sup>) mice show attenuation of AAIA. We also demonstrate that gene deletion or silencing of Nrdc in mouse macrophages or human monocytic cells results in reduction of TNF-α shedding. Importantly, the level of NRDC is increased in synovial fluid from RA patients compared with that from osteoarthritis (OA) patients. Moreover, intra-articular injection of anti-Nrdc small interfering RNA (siRNA) ameliorates CAIA. Together, these data suggest that NRDC controls AAIA via the regulation of TNF-α shedding and could be a new therapeutic target for RA treatment.

**RESULTS**

**Nrdc-deficient mice are resistant to CAIA**

To explore the role of NRDC in RA, we compared wild-type (WT) and Nrdc<sup>−/−</sup> mice with a BALB/c background using the CAIA model. After the intraperitoneal administration of a five-clone cocktail of monoclonal anti-type II collagen antibodies, we assessed the severity of arthritis daily for 2 weeks. The onset of arthritis was delayed (on day 3 in WT mice and on day 6 in Nrdc<sup>−/−</sup> mice, respectively) and the average of arthritis score was significantly and markedly lower in Nrdc<sup>−/−</sup> mice (figure 1A,B). Ankle thickness was also significantly less in Nrdc<sup>−/−</sup> mice from days 4 to 9 compared with that in WT mice. Histological examination of the ankle joints demonstrated that synovial hypertrophy with infiltration of inflammatory cells and bone and cartilage erosion were reduced or absent in Nrdc<sup>−/−</sup> mice (figure 1C). These results suggest that NRDC is crucial for AAIA development and progression.

**Macrophage-specific Nrdc-deficient mice are resistant to CAIA**

Because macrophages play an important role in the pathogenesis of RA, we next generated Nrdc<sup>ΔM</sup> mice by crossing Nrdc<sup>flm/flm</sup> mice with Lys2 Cre mice, in which Cre recombinase is expressed under the control of the lysosome 2 gene (Lys2) promoter. Because the Nrdc<sup>flm/flm</sup> and Nrdc<sup>ΔM</sup> mice have a C57BL/6/6 genetic background, which is more resistant to CAIA than BALB/c, we administered 2.5 times more antibody to Nrdc<sup>flm/flm</sup> and Nrdc<sup>ΔM</sup> mice for the CAIA experiments compared with the amount that was used for the Nrdc<sup>−/−</sup> mice. The results showed that the onset of arthritis was delayed and the severity of arthritis was markedly reduced in Nrdc<sup>ΔM</sup> mice compared with controls (figure 2A, B). As was the case for Nrdc<sup>−/−</sup> mice, synovial hypertrophy and bone erosion were attenuated in Nrdc<sup>ΔM</sup> mice (figure 2C). These findings demonstrated that macrophage-specific deletion of NRDC almost completely recapitulated the resistance of Nrdc<sup>−/−</sup> mice to CAIA.

**Arthritis in the K/Bxn STA model is attenuated in Nrdc<sup>ΔM</sup> mice**

To confirm the role of NRDC in autoimmune arthritis, we examined Nrdc<sup>flm/flm</sup> and Nrdc<sup>ΔM</sup> mice in another murine model, the K/Bxn STA model. K/Bxn mouse serum has been reported to strongly induce arthritis in a wide range of mouse strains. As shown in figure 2D,E,
CAIA is attenuated in Nrdc<sup>−/−</sup> mice. (A) Photographs of the hind paws 4 days and 7 days after the induction of CAIA. Upper panels, wild-type (WT); lower panels, Nrdc<sup>−/−</sup> mice. (B) Arthritis score (upper) and ankle thickness (lower) were measured daily after the induction of CAIA. n=5 per genotype (mean ± SEM). *p<0.05; **p<0.01, Welch’s t-test. (C) H&E staining of the ankle joints 14 days after the induction of CAIA in WT (upper panels) and Nrdc<sup>−/−</sup> (lower panels) mice. Scale bars: 500 µm in the 40x magnification and 200 µm in the 100x magnification. Symbols in the 100x magnification images: arrow, bone erosion; arrow head, cartilage erosion; *, hypertrophic synovium.

K/BxN STA was significantly attenuated in Nrde<sup>dcm</sup> mice up to day 8 after injection. In contrast, there were no significant differences between Nrde<sup>lox/lox</sup> and Nrde<sup>dcm</sup> mice in the arthritis score after day 9 or in ankle thickness, although both values tended to be lower in Nrde<sup>dcm</sup> mice (figure 2D,E). The histology of the hind paws at day 14 demonstrated that the synovial hypertrophy with infiltration of inflammatory cells, bone erosion and cartilage erosion were equivalently observed in both Nrde<sup>lox/lox</sup> mice and Nrde<sup>dcm</sup> mice (figure 2F), which is consistent with the results of arthritis score and ankle thickness. Collectively, these data demonstrated that NRDC deficiency in macrophages attenuated the severity of arthritis in two different experimental models of AAIA.

Secretion of TNF-α from macrophages and monocytic cells is reduced by the deletion of Nrdc

Because macrophages are a major source of TNF-α in AAIA<sup>34</sup> and NRDC facilitates ectodomain shedding of TNF-α<sup>23</sup> we hypothesised that the attenuation of AAIA in Nrde<sup>−/−</sup> mice and Nrde<sup>dcm</sup> mice was due to the impairment of ectodomain shedding of TNF-α in macrophages. To test this hypothesis, we first examined TNF-α secretion from NRDC-deficient macrophages. We harvested bone marrow derived macrophages (BMDMs) from

Nrdc<sup>fox/fox</sup> and Nrdc<sup>delM</sup> mice and confirmed that NRDC protein expression was remarkably reduced in BMDMs from Nrdc<sup>delM</sup> mice (figure 3A). BMDMs were stimulated with or without a low concentration (10 ng/mL) of lipopolysaccharide (LPS), then the concentration of secreted TNF-α in the supernatants and the levels of TNF-α messenger RNA (mRNA) in BMDMs were examined. The results showed that there was no significant
Secretion of TNF-α from macrophages and monocytic cells were reduced by the deletion of Nrdc. (J) F4/80 expression in peritoneal macrophage (PMs). Filled histogram, isotype control; open histogram, F4/80. Representative histograms out of three independent experiments are shown. (K) NRDC expression in PMs, isolated from Nrdc<sup>lox/lox</sup> (left) and Nrdc<sup>delM</sup> mice (right) after the reverse passive Arthus reaction, was examined by Western blot. β-Actin was used as a loading control. (L) Membrane-bound TNF-α was stained and analysed by flow cytometry. Filled histogram, unstimulated control; blue open histogram, Nrdc<sup>lox/lox</sup>, red open histogram, Nrdc<sup>delM</sup>. Representative histograms out of three independent experiments are shown. (M) Measurement of secreted TNF-α concentration in the peritoneal lavage of Nrdc<sup>lox/lox</sup> (n=5), Nrdc<sup>delM</sup> (n=5) and control (n=4) mice. *p<0.05; **p<0.01, Welch’s t-test.
difference in the mRNA level, but that there was a significant decrease in TNF-α secretion from NRDC-deficient BMDMs at 3 hours after stimulation (figure 3B,C). Because impairment of TNF-α shedding leads to accumulation of membrane-bound TNF-α,⁵ we analysed the cell surface expression of TNF-α on BMDMs by flow cytometry and found that membrane-bound TNF-α was increased in BMDMs from Nrdc<sup>delM</sup> mice (figure 3D). ADAM17 is essential for TNF-α shedding, and we previously reported that NRDC enhances the sheddase activity of ADAM17 via a direct interaction. Consistent with this, there were no significant differences in ADAM17 mRNA levels between BMDMs from Nrdc<sup>fl</sup> and Nrdc<sup>delM</sup> mice (figure 3E).

We next assessed the effect of NRDC gene knockdown in a human monocytic cell line, THP-1. Efficient inhibition of NRDC mRNA and protein levels was confirmed in THP-1 cells infected with lentiviral vectors expressing RNAi targeting NRDC (figure 3F,G). LPS-induced TNF-α secretion in the supernatants was significantly decreased by gene knockdown of NRDC, whereas TNF-α mRNA levels and TNF-α protein concentrations in the cell lysates did not differ between control and NRDC-knocked down cells (figure 3H,I). Together, our results in mouse macrophages and human monocytic cells suggested that TNF-α activation via ectodomain shedding was inhibited by the deletion of NRDC.

To assess the in vivo role of NRDC on TNF-α secretion in a way more relevant to disease, we examined the effect of immunocomplexes (ICs) on TNF-α secretion. In the mechanism of AAIA, inflammatory cells are activated by ICs that are deposited in the joints. To mimic this response, we applied a reverse passive Arthus reaction peritonitis⁶ and a model to Nrdc<sup>fl</sup> and Nrdc<sup>delM</sup> mice. In this model, ovalbumin (OVA) and anti-OVA antibody are administered separately, and then combine to make ICs that trigger complement pathways. We confirmed that TNF-α was impaired in NRDC-deficient macrophages. NRDC increased in synovial fluid of patients with RA

To assess the pathophysiological role of NRDC in patients, we collected synovial fluid from patients with RA or OA during joint surgery. Intriguingly, we found a remarkable and significant elevation of the level of NRDC and TNF-α in synovial fluid from RA patients compared with that from OA patients (table 1, figure 4A,B).

Notably, the level of TNF-α in RA synovial fluid had a tendency of positive correlation with the level of NRDC (p=0.054), suggesting the causative role of NRDC in TNF-α elevation (figure 4C). We next analysed the association of NRDC levels in RA synovial fluid with the patients’ clinical condition. Interestingly, NRDC levels showed a significant but modest correlation with CRP levels, but no correlations with other factors including ESR, disease activity (disease activity score 28 (DAS28)-ESR), RF or ACPA (figure 4D and data not shown). These data suggested that NRDC could be a unique synovial fluid marker for the differential diagnosis of late RA and late OA.

**Gene silencing of Nrdc in the ankle joints ameliorated CAIA in WT mice**

To confirm the pathological role in vivo of NRDC in autoimmune arthritis, we examined whether local gene silencing of Nrdc ameliorated CAIA. We first tested three siRNAs targeting Nrdc in three different cell lines (RAW264.7, WEHI 13 VAR and mouse embryonic fibroblasts) and selected the siRNA with the best silencing efficacy (siRNA3) (figure 5A). This anti-Nrdc siRNA was injected into the left ankle joint of mice 2 days after CAIA induction, while negative control siRNA was injected into the right ankle joint. The results showed that the severity of arthritis was clearly reduced in the left joint (anti-NRDC siRNA) compared with the right joint (control siRNA) (figure 5C). The measurement of ankle thickness revealed that anti-Nrdc siRNA significantly ameliorated CAIA from days 3 to 8 and days 12 to 14 (figure 5D).

DISCUSSION

In this study, we demonstrate for the first time in vivo that NRDC plays important roles in autoimmune arthritis. First, Nrdc−/− mice were resistant to CAIA, and resistance to two models of AAIA, CAIA and K/BxN STA, was confirmed in Nrdc−/− mice, indicating that NRDC in macrophages is crucial for the pathogenesis of autoimmune arthritis. In both CAIA and K/BxN STA models, inhibition of TNF-α has been shown to attenuate arthritis.4,18 Given that macrophages are a major source of TNF-α mRNA was not significantly increased in AAIA models. Using BMDMs, PMs and THP-1 cells, we showed that NRDC enhances ectodomain shedding of TNF-α via activation of ADAM17.22–24 Interestingly, the peptidase activity of NRDC is not directly to ADAM17 and enhance its enzymatic activity. Although we cannot assign NRDC as a wide range of membrane proteins including EGF receptor ligands and Notch,41 which may cause side effects of ADAM17 inhibition. However, ADAM17 cleaves not only TNF-α but also a wide range of membrane proteins including EGF receptor ligands and Notch,18 which may cause side effects of ADAM17 inhibitor treatment in the skin, intestine and liver.34,42

These previous findings prompted us to examine the role of NRDC in autoimmune arthritis, and we found that inhibition of NRDC had a protective effect against arthritis.6 Inhibition of NRDC could have the potential to reduce only excessive TNF-α production and secretion. Thus, anti-NRDC therapy might cause adverse effects, mainly infections, because a physiological level of TNF-α secretion is necessary for the normal inflammatory response. As we show here, gene deletion or silencing of NRDC in macrophages and monocytic cells did not affect their baseline level of constitutive TNF-α production, suggesting that it is extracellular function as an enhancer of ectodomain shedding. NRDC-mediated regulation of ectodomain shedding of various membrane proteins including HB-EGF, neuregulin1 and amyloid precursor protein.22,24 Other than TNF-α, several membrane proteins considered to be important for RA pathogenesis, such as TNF receptors and IL-6 receptors, are also functionally regulated by ectodomain shedding. NRDC-mediated regulation of the shedding of these molecules might contribute to the attenuation of arthritis by the deletion of NRDC.

Apart from its extracellular function as an enhancer of ectodomain shedding, a nuclear function of NRDC as a transcriptional coregulator has been recently clarified. The roles of NRDC in transcriptional regulation were illustrated by the interaction of NRDC with various nuclear proteins such as histone deacetylase 3, peroxisome proliferator-activated receptor gamma coactivator 1-α and islet1.43–45 Intriguingly, the nuclear function of NRDC is crucially involved in adaptive thermogenesis44 and insulin secretion in vivo.45 Although we cannot exclude a possible involvement of nuclear NRDC in AAIA, we demonstrate here that mRNA levels of TNF-α and ADAM17 in macrophages are not affected by the inhibition of NRDC, suggesting that it is extracellular NRDC that mainly regulates AAIA.

Another limitation of this study is that we have not clarified NRDC function in neutrophils, which have a role in the pathogenesis of AAIA.35 Because the Lyz2 inflammation. These results suggest that NRDC plays important roles not only in mouse experimental models of RA but also in RA patients, and therefore that gene-targeted therapy with RNAsi has potential in the treatment of RA.38 Intra-articular injection of anti-TNF-α siRNA was shown to inhibit collagen-induced arthritis in mice,39 and intravenous administration of double-stranded miR-151 reduced arthritis in SKG mice via down-regulation of neutrophil chemotaxis.40 We show here that intra-articular injection of anti-Nrdc siRNA ameliorated CAIA. In this experiment, arthritis was induced more rapidly than without intra-articular injection, probably because of the inflammatory response against injected reagents or trauma associated with the injection. This significant attenuation of arthritis by anti-Nrdc siRNA provided an indication of a novel treatment for RA. Although biologic TNF-α blockers are widely used for the management of RA patients, complete inhibition of TNF-α might cause adverse effects, mainly infections, because a physiological level of TNF-α secretion is necessary for the normal inflammatory response. As we show here, gene deletion or silencing of NRDC in macrophages and monocytic cells did not affect their baseline level of constitutive TNF-α production and secretion. Thus, anti-NRDC therapy could have the potential to reduce only excessive TNF-α secretion. In a similar sense, ADAM17 could be an alternative target for controlling TNF-α secretion. However, ADAM17 cleaves not only TNF-α but also a wide range of membrane proteins including EGF receptor ligands and Notch,41 which may cause side effects of ADAM17 inhibitor treatment in the skin, intestine and liver.34,42

In terms of substrates, NRDC also enhances ectodomain shedding of various membrane proteins including HB-EGF, neuregulin1 and amyloid precursor precursor.22,24 Other than TNF-α, several membrane proteins considered to be important for RA pathogenesis, such as TNF receptors and IL-6 receptors, are also functionally regulated by ectodomain shedding. NRDC-mediated regulation of the shedding of these molecules might contribute to the attenuation of arthritis by the deletion of NRDC.

Apart from its extracellular function as an enhancer of ectodomain shedding, a nuclear function of NRDC as a transcriptional coregulator has been recently clarified. The roles of NRDC in transcriptional regulation were illustrated by the interaction of NRDC with various nuclear proteins such as histone deacetylase 3, peroxisome proliferator-activated receptor gamma coactivator 1-α and islet1.43–45 Intriguingly, the nuclear function of NRDC is crucially involved in adaptive thermogenesis44 and insulin secretion in vivo.45 Although we cannot exclude a possible involvement of nuclear NRDC in AAIA, we demonstrate here that mRNA levels of TNF-α and ADAM17 in macrophages are not affected by the inhibition of NRDC, suggesting that it is extracellular NRDC that mainly regulates AAIA.

Another limitation of this study is that we have not clarified NRDC function in neutrophils, which have a role in the pathogenesis of AAIA.35 Because the Lyz2

gene is expressed not only in macrophages but also in
neutrophils, NRDC in neutrophils should be deleted in
Nrdc<sup>-/-</sup> mice.

In summary, our results demonstrated for the first
time that NRDC is involved in AAIA at least partially
via enhancement of TNF-α shedding in macrophages.
NRDC levels in synovial fluid are increased in RA patients

TNF-α is enhanced by nardylisin via activation of ADAM proteases.

shedding of heparin-binding epidermal growth factor-like growth factor
trough activation of tumor necrosis factor-alpha-converting enzyme.

of a dibasic selective metalloendopeptidase from rat testes that
cleaves at the amino terminus of arginine residues. J Biol Chem

a metalloendopeptidase as a prototype of a class of processing

27. Nishi E, Prat A, Hospital V, et al. N-arginine dibasic convertase is
a specific receptor for heparin-binding EGF-like growth factor that
mediates cell migration. EMBO J 2001;20:3342–50.

prevents the development of steatohepatitis and liver fibrotic

35. McIlwain DR, Lang PA, Maretzky T, et al. iRhom2 regulation of TACE controls TNF-mediated protection against Listeria and responses to LPS. *Science* 2012;335:229–32.

Nardilysin is involved in autoimmune arthritis via the regulation of tumour necrosis factor alpha secretion

RMD Open 2017 3:
doi: 10.1136/rmdopen-2017-000436
