Measurements of the absolute branching fractions of $B^+ \rightarrow X_c \bar{K}^+$ and $B^+ \rightarrow \bar{D}/(C_3)\pi^{+}$ at Belle

(The Belle Collaboration)
We present the measurement of the absolute branching fractions of $B^+ \to X_{c\bar{c}}K^+$ and $B^+ \to \bar{D}^{(*)0}\pi^+$ decays, using a data sample of $772 \times 10^6 B\bar{B}$ pairs collected at the $\Upsilon(4S)$ resonance with the Belle detector at the KEKB asymmetric-energy $e^+e^-$ collider. Here, $X_{c\bar{c}}$ denotes $\eta_c$, $J/\psi$, $\chi_{c0}$, $\chi_{c1}$, $\eta_c(2S)$, $\psi(2S)$, $\psi(3770)$, $X(3872)$, and $X(3915)$. We do not observe significant signals for $X(3872)$ or $X(3915)$ and set the 90% confidence level upper limits at $B(B^+ \to X(3872)K^+) < 2.6 \times 10^{-4}$ and $B(B^+ \to X(3915)K^+) < 2.8 \times 10^{-4}$. These represent the most stringent upper limit for $B(B^+ \to X(3872)K^+)$ to date and the first limit for $B(B^+ \to X(3915)K^+)$. The measured branching fractions for $\eta_c$ and $\eta_c(2S)$ are the most precise to date, $B(B^+ \to \eta_cK^+) = (12.0 \pm 0.8 \pm 0.7) \times 10^{-4}$ and $B(B^+ \to \eta_c(2S)K^+) = (4.8 \pm 1.1 \pm 0.3) \times 10^{-4}$, where the first and second uncertainties are statistical and systematic, respectively.

DOI: 10.1103/PhysRevD.97.012005
II. DATA SAMPLES AND THE BELLE DETECTOR

We use a data sample of \(772 \times 10^6\) \(B\bar{B}\) pairs recorded with the Belle detector at the KEKB asymmetric-energy \(e^+e^-\) collider [12]. The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL) located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return located outside of the coil is instrumented to detect \(K_S^0\) mesons and to identify muons. The Belle detector is described in detail elsewhere [13].

We use Monte-Carlo (MC) simulated events generated using EVTGEN [14] and JETSET [15] that include QED final-state radiation [16]. The events are then processed by a detector simulation based on GEANT3 [17]. We produce signal MC events to obtain the reconstruction efficiency and the mass resolution for signal events. We also use background MC samples to study the missing-mass distribution in the background process \(\Upsilon(4S) \rightarrow B\bar{B}\) and \(e^+e^- \rightarrow q\bar{q} (q = u, d, s, c and b)\) with statistics 6 times that of data.

III. ANALYSIS OVERVIEW

In this analysis, we fully reconstruct one of the two charged \(B\) mesons (\(B_{\text{tag}}\)) via hadronic states and require at least one charged kaon or pion candidate among the charged particles not used for the \(B_{\text{tag}}\) reconstruction. The kaon or pion, coming from the other charged \(B\) meson, \(B_{\text{tag}}\), is required to have a charge opposite that of \(B_{\text{tag}}\). The \(B_{\text{tag}}\) is reconstructed in one of 1104 hadronic decays using a hierarchical hadronic full reconstruction algorithm based on the NeuroBayes neural-network package [18]. The quality of a \(B_{\text{tag}}\) candidate is represented by a single NeuroBayes output-variable classifier (\(O_{\text{NB}}\)), which includes event-shape information to suppress continuum events. We require \(O_{\text{NB}}\) to be greater than 0.01, which retains 90% of true \(B_{\text{tag}}\) candidates and rejects 70% of fake \(B_{\text{tag}}\) candidates. The beam constrained mass \(M_{\text{bc}} = \sqrt{E_{\text{beam}}^2/c^4 - |P_{\text{tag}}^2/c^2|}\) where \(E_{\text{beam}}\) and \(P_{\text{tag}}\) are the beam-energy and the reconstructed \(B_{\text{tag}}\) three-momenta, respectively, in the center-of-mass frame, is required to be greater than 5.273 GeV/c².

About 18% of the events contain multiple \(B_{\text{tag}}\) candidates that pass all the selection criteria. In such an event, the \(B_{\text{tag}}\) with the greatest \(O_{\text{NB}}\) is retained. The \(B_{\text{tag}}\) reconstruction efficiency is roughly 0.3%. Figure 1 shows the \(M_{\text{bc}}\) distribution for data with the \(O_{\text{NB}}\) requirement applied. The selections of the charged kaon and pion daughters of \(B_{\text{tag}}\) are performed based on vertex information from the tracking system (SVD and CDC) and likelihood values \(L_K\) and \(L_\pi\) provided by the hadron identification system, ionization loss in the CDC, the number of detected Cherenkov photons in the ACC, and the time-of-flight measured by the TOF [19]. A charged track is required to have a point of closest approach to the interaction point that is within 5.0 cm along the \(z\) axis and 0.40 cm in the transverse (\(r\phi\)) plane. The \(z\) axis is opposite the positron beam direction. A track is identified as a kaon (pion) if the likelihood ratio \(L(K:p)\) (\(L(\pi:K)\)) is greater than 0.6. The likelihood ratio is defined as \(L(i:j) = L_i/(L_i + L_j)\). The efficiencies of hadron identification are about 90% for both pions and kaons. The momentum-averaged probability to misidentify a pion (kaon) track as a kaon (pion) track is about 9% (10%). We identify the signal as a peak at the nominal \(X_{\text{c3}}\) or \(D^{\pm}\) mass in the distribution of missing mass,

\[
M_{\text{miss}} = \sqrt{(p_{e^-}^* - p_{\text{tag}}^* - p_{h}^*)^2/c},
\]

where \(M_{\text{miss}}\) is the missing mass recoiling against the hadron \(h\) (\(\pi^+\) or \(K^+\)), and \(p_{e^-}, p_{\text{tag}},\) and \(p_{h}\) are the four-momenta of the electron-positron initial state, \(B_{\text{tag}},\) and \(h\), respectively, in the center-of-mass frame. The probability to observe multiple kaon or pion candidates in the \(M_{\text{miss}}\) range of interest (2.6 GeV/c² < \(M_{\text{miss}}\) < 4.1 GeV/c² and 2.5 GeV/c²) in an event is 2.8% and 0.3%, respectively. We do not apply a best-candidate selection if multiple candidates are found.

The beam-energy resolution is a dominant contribution to the \(M_{\text{bc}}\) resolution, and event-by-event fluctuations of \(M_{\text{bc}}\) from the nominal \(B\) meson mass are directly correlated to the event-by-event fluctuation of the beam energy. We apply a correction to account for the event-by-event fluctuation of the beam energy using a linear relation to \(M_{\text{bc}}\). The corrected beam-energy improves the missing mass resolution by 8%, 4%, and 2% for \(X(3872), J/\psi,\) and...
FIG. 2. Observed $M_{\text{miss}}(\pi^+)$ distribution. Points with error bars represent data. The solid, dashed, and dotted lines represent the total fit result, the contribution from $D^0$ and $\bar{D}^0$, and the contribution from the background, respectively.

$D^0$, respectively. The validity of the beam-energy correction is checked using high-statistics samples $B^+ \rightarrow D^{(*)0}\pi^+$, $B^+ \rightarrow D^{(*)0}\pi^+\pi^+$, and $B^+ \rightarrow J/\psi K^+$ samples. We divide the samples into two sets with $M_{\text{mc}}$ smaller or larger than the nominal $B^+$ mass [10]. The peak positions in the $M_{\text{miss(h)}}$ distribution for both data sets without the beam-energy correction are significantly different from their expected masses and are consistent within uncertainty after the correction. We blinded the missing mass distribution in the range $3.3 \text{ GeV}/c^2 < M_{\text{miss}}(\pi^+) < 4.0 \text{ GeV}/c^2$ until the analysis procedure was fixed. Branching fractions are obtained using the following equations,

$$B = \frac{N_{\text{sig}}}{2N_{B^+}e},$$

$$N_{B^\pm} = N_{\Upsilon(4S)}B(\Upsilon(4S) \rightarrow B^+B^-),$$

where $N_{\text{sig}}$ is the signal yield obtained from the fit to the missing mass distribution, $e$ is the reconstruction efficiency for $B_{\text{sig}}$ and pion or kaon in $B_{\text{sig}}$, and $N_{\Upsilon(4S)}$ is the number of accumulated $\Upsilon(4S)$ events. We use a value of 0.514 for $B(\Upsilon(4S) \rightarrow B^+B^-)$ [10]. The factor of two in Eq. (2) originates from the inclusion of the charge-conjugate mode.

### IV. ANALYSIS OF $B^+ \rightarrow \bar{D}^{(*)0}\pi^+$ DECAY

Figure 2 shows the observed $M_{\text{miss}}(\pi^+)$ distribution, where clear peaks corresponding to $D^0$ and $\bar{D}^0$ are visible. In order to extract the signal $\bar{D}^{(*)0}$ yields, a binned likelihood fit is performed. The probability density function (PDF) for the signal peak is the sum of three Gaussian functions based on a study of large simulated samples of signal decays. The mean value for one Gaussian function is allowed to differ from that of the other two to accommodate for the tail in high-mass regions resulting from $B_{\text{tag}}$ decays with photons. The relative weights of the three Gaussian functions are fixed to the values obtained from the signal MC. We introduce two parameters: the global offset of the mean $(\mu_{\text{data}} - \mu_{\text{MC}})$ and the global resolution scale factor $(\sigma_{\text{data}}/\sigma_{\text{MC}})$ to accommodate for a possible difference in the shape in the signal MC and data. The PDF for background events is represented by a second-order exponential: $\exp(ax + bx^2)$, where $a$ and $b$ are free parameters in the fit. The validity of using this function as a background PDF is confirmed by fitting to the background MC and sideband data, which is defined within the region $5.22 \text{ GeV}/c^2 < M_{\text{bc}} < 5.26 \text{ GeV}/c^2$. The fit returns a reasonable $\chi^2/\text{ndf}$, where ndf is number of degree of freedom. $\chi^2$ is not improved by increasing the exponential order. The mass range above $2.3 \text{ GeV}/c^2$ is not included in the fit to avoid contributions from excited $D$ mesons.

Table I summarizes the branching fraction measurements for $B^+ \rightarrow \pi^+\bar{D}^{(*)0}$ decays. The values of $(\mu_{\text{data}} - \mu_{\text{MC}})$ and $(\sigma_{\text{data}}/\sigma_{\text{MC}})$ are found to be quite consistent at 0 MeV/$c^2$ and 1, respectively, indicating that the signal MC describes the signal shape well. The measured branching fractions are consistent with the world averages [10] within 1.1σ taking into account the fact that almost all past measurements assumed $B(\Upsilon(4S) \rightarrow B^+B^-) = 0.5$.

### V. ANALYSIS OF $B^+ \rightarrow X_{c\bar{c}}K^+$ DECAY

Figure 3 shows the observed and fitted $M_{\text{miss}}(K^+)$ distributions. We again perform a binned likelihood fit to extract the signal $X_{c\bar{c}}$ yields. In the analysis of the high-statistics sample of $B^+ \rightarrow \bar{D}^{(*)0}\pi^+$, we confirm that the signal shape is consistent between data and MC. Therefore, we fix the signal PDF to be the histogram PDF from signal MC generated with the mass and natural width of the $X_{c\bar{c}}$ states fixed to the world averages [10]. We consider nine $X_{c\bar{c}}$ in the fit: $\eta_c$, $J/\psi$, $\chi_{c0}$, $\chi_{c1}$, $\eta_c(2S)$, $\psi(2S)$, $\psi(3770)$,

</table>

$X(3872)$, and $X(3915)$. We do not include $h_{c}$ and $X_{c2}$ because their branching fractions are measured to be very small [10]: $B(B^{+} \rightarrow K^{+} h_{c}) < 3.8 \times 10^{-5}$ at 90% C.L. and $B(B^{+} \rightarrow K^{+} X_{c2}) = (1.1 ± 0.4) \times 10^{-5}$. The background PDF is a second-order exponential, as for $B^{+} \rightarrow \pi^{+}D^{+(0)}$, and is again validated with background MC and the data sideband. The statistical significance of each $X_{c3}$ state is determined from the log-likelihood ratio $-2 \ln (\mathcal{L}_{0}/\mathcal{L})$, where $\mathcal{L}_{0}$ ($\mathcal{L}$) is the likelihood for the fit without (with) the signal component. When we evaluate the significance for a $X_{c3}$ state, the other $X_{c3}$ states are included in the fit. The branching fractions are determined using Eq. (2). For $X_{c0}$, $\psi(3770)$, and $X(3872)$, the significances are smaller than three standard deviations ($\sigma$). We also set 90% C.L. upper limit for branching fractions to these states using the $CL_{S}$ technique [20].

The results are summarized in Table II. The upper limit for $B(B^{+} \rightarrow X(3872)K^{+})$ is the most stringent to date. The upper limit for the $B(B^{+} \rightarrow X(3915)K^{+})$ is determined for the first time. The measurements for $B(B^{+} \rightarrow \eta_{c}K^{+})$ and $B(B^{+} \rightarrow \eta_{c}(2S)K^{+})$ are the most precise to date. In particular, this is the first significant measurement of $B(B^{+} \rightarrow \eta_{c}(2S)K^{+})$. For $B(B^{+} \rightarrow \psi(3770)K^{+})$, we do not see a significant signal and the measured value is smaller than world average by 2.7$\sigma$. For the other measurements, the values are consistent with world averages within 1.7$\sigma$.

In Fig. 3(c), we see an enhancement near 3545 MeV/c$^{2}$, where no known charmonium state exists. We attempt to fit this by including an additional contribution using signal MC PDF with a mass of 3545 MeV/c$^{2}$ and a natural width of 0 MeV. An offset for the peak position is introduced as a free parameter. The signal yield is 738 ± 189 events at the peak position of 3544.2 ± 2.8 MeV/c$^{2}$, which is 4.3$\sigma$ lower than the mass of the $X_{c2}$. The $-2 \ln (\mathcal{L}_{0}/\mathcal{L})$ value is 16.5. Since the signal region is very wide compared to the experimental resolution, we estimate the probability to observe such an enhancement in a single experiment. We perform one million pseudoexperiments in which background events are generated with the same shape and yield as data. Multiple fits, each including signal with a natural width of zero and a mass value incremented by 1 MeV/c$^{2}$ across the fit range for successive fits, are performed and the highest $-2 \ln (\mathcal{L}_{0}/\mathcal{L})$ in one pseudoexperiment is retained. The probability to observe an enhancement with $-2 \ln (\mathcal{L}_{0}/\mathcal{L})$ greater than 16.5 is 0.43%, which corresponds to a global significance of 2.8$\sigma$. We, therefore, conclude that the enhancement is not significant.

VI. SYSTEMATIC UNCERTAINTY

A summary of the systematic uncertainties for each $X_{c3}$ and $D^{+(0)}$ state is provided in Table III. We consider the following systematic uncertainties for the branching fraction measurements. The systematic uncertainty for the efficiency of the charged hadron identification is estimated from the yield of $D^{+} \rightarrow D^{0} \pi^{+}$, $D^{0} \rightarrow K^{-}\pi^{+}$ with and without the hadron identification requirements. We apply a correction factor to the particle identification efficiencies based on the ratio of the efficiencies found in the MC and data samples. The uncertainty of the correction factor is treated as the systematic uncertainty. The systematic uncertainty due to the charged track reconstruction efficiency is estimated using the decay chain $D^{+} \rightarrow \pi^{+}D^{0}$, $D^{0} \rightarrow \pi^{+}\pi^{-}K_{S}^{0}$, and $K_{S}^{0} \rightarrow \pi^{+}\pi^{-}$ where $K_{S}^{0}$ is either partially or fully reconstructed. The ratio between the yields of partially and fully reconstructed signals are compared between data and MC; the difference of 0.35% per track is taken as the systematic uncertainty. The systematic uncertainty from the reconstruction efficiency of $B_{tag}$ is estimated using a hadronic-tag analysis in which $B_{tag}$ decays to $D^{+(0)}l\nu$, where $l$ is electron or muon [21]. The yield for this signal is compared between data and MC, and the difference is implemented as a correction factor for each $B_{tag}$ decay mode. The averaged correction factor used in this analysis is 0.76 independent of $X_{c3}$. The signal and background efficiencies are multiplied by this factor. The main origin of the correction factor is understood to result from the fact that branching fractions for some of the $B_{tag}$ decays in the MC generation are outdated and inconsistent with the most recent measurements. Furthermore, this correction factor is also determined in the $B^{-} \rightarrow \tau^{-}\nu$...
The uncertainty for the K± mass corresponds to a systematic uncertainty of 1.2%. The systematic uncertainty on the background assumption is not taken into account in Ref. [21]. These are implemented in this analysis. The world average of the background MC and the signal MC, respectively. The reconstruction efficiency of the background and signal shapes determined from the background MC and the signal MC, respectively. The background yields are taken from the sideband region of ECL for the data defined as

\[ \chi_{r}^{2} / \nu \]  

The systematic uncertainty arising due to the mass and width of each state is estimated by performing fits while varying the mass and width by the world-average uncertainties [10]. The systematic uncertainty on the fitter bias is estimated by performing pseudoexperiments. We generate pseudodata from the background and signal shapes determined from the background MC and the signal MC, respectively. The background yields are taken from the sideband region of the signal MC. We perform a binned likelihood fit to extract the signal yields in each pseudoexperiment. The difference between the mean of the extracted signal yields and the input mass value is taken as the systematic uncertainty. The systematic uncertainty in the branching fraction of each Xc state is limited, a systematic uncertainty is assigned in the following way. For each Xc state, the sum of the known branching fractions is equal to 100%. In the default estimation of the branching fraction, unknown decay modes are filled with decays into uū, d̅d, and s̅s, that hadronize via PYTHIA. The systematic uncertainty is estimated by eliminating the PYTHIA-generated decay and taking the difference with the nominal efficiency. For X(3872) and X(3915), the PYTHIA decay is not implemented by default. Therefore, the systematic uncertainty is estimated by implementing the PYTHIA decay with a branching fraction of 50%. The systematic uncertainty on the background assumption is estimated by performing a fit after changing the order of the exponential background’s polynomial exponent from quadratic to cubic. We perform a fit including the π0, ρ0, and ω, that hadronize via PYTHIA. The systematic uncertainty in the bran...
The second uncertainty is dominated by the measurement of $B(B^+ \rightarrow X(3872)K^+)$, which is more stringent than the one determined by BABAR [11] ($3.2 \times 10^{-4}$). The lower limit of $B(X(3872) \rightarrow f)$ is based on BABAR’s measurement. Our result improves these lower limits. We set the 90% C.L. upper limit of $B(B^+ \rightarrow X(3915)K^+)$ as $2.8 \times 10^{-4}$ for the first time.

We measure $B(B^+ \rightarrow \eta K^+) = (12.0 \pm 0.8 \pm 0.7) \times 10^{-4}$ and $B(B^+ \rightarrow \eta_c(2S)K^+) = (4.8 \pm 1.1 \pm 0.3) \times 10^{-4}$, which are the most accurate measurements to date. In particular, this is the first significant measurement for $B(B^+ \rightarrow \eta_c(2S)K^+)$. The current world average of $B(\eta_c(2S) \rightarrow K\bar{K}\pi)$ is $(1.9 \pm 0.4 \pm 1.1)\%$ [10], where the second uncertainty is dominated by the measurement of $B(B^+ \rightarrow \eta_c(2S)K^+) = (3.4 \pm 1.8) \times 10^{-4}$ by BABAR [11]. Our measurement significantly improves the precision of $B(\eta_c(2S) \rightarrow K\bar{K}\pi)$. In addition, this measurement can contribute to many other decays involving the $\eta_c(2S)$ such as $\psi(2S) \rightarrow \gamma\eta_c(2S)$ by BESIII [23] and $\eta_c(2S) \rightarrow p\bar{p}$ by LHCb [24]. Finally, we measure $B(B^+ \rightarrow D^0\pi^+) = (4.34 \pm 0.10 \pm 0.25) \times 10^{-3}$ and $B(B^+ \rightarrow D^{*0}\pi^+) = (4.82 \pm 0.12 \pm 0.35) \times 10^{-3}$, which are consistent with the world averages [10]. The latter is the most precise measurement from a single experiment.

We thank the KEKB group for the excellent operation of the accelerator; the KEK cryogenics group for the efficient operation of the solenoid; and the KEK computer group, the National Institute of Informatics, and the Pacific Northwest National Laboratory (PNNL) Environmental Molecular Sciences Laboratory (EMSL) computing group for valuable computing and Science Information NETwork 5 (SINET5) network support. We acknowledge support from the Ministry of Education, Culture, Sports, Science, and Technology (MEXT) of Japan, the Japan Society for the Promotion of Science (JSPS), and the Tau-Lepton Physics Research Center of Nagoya University; the Australian Research Council; Austrian Science Fund under Grant No. P 26794-N20; the National Natural Science Foundation of China under Contracts No. 11435013, No. 11475187, No. 11521505, No. 11575017, No. 11675166, No. 11705209; Key Research Program of Frontier Sciences, Chinese Academy of Sciences (CAS), Grant No. QYZDJ-SSW-SLH011; the CAS Center for Excellence in Particle Physics (CCEPP); Fudan University Grant No. JIH5913023, No. IDH5913011/003, No. JIH5913024, No. IDH5913011/002; the Ministry of Education, Youth and Sports of the Czech Republic under Contract No. LTT17020; the Carl Zeiss Foundation, the Deutsche Forschungsgemeinschaft, the Excellence Cluster Universe, and the VolkswagenStiftung; the Department of Science and Technology of India; the Istituto Nazionale di Fisica Nucleare of Italy; National Research Foundation (NRF) of Korea Grants No. 2014R1A2A2A01005286, No. 2015R1A2A2A01003280, No. 2015H1A2A1033649, No. 2016R1D1A1B01010135, No. 2016K1A3A7A09005 603, No. 2016R1D1A1B02012900; Radiation Science Research Institute, Foreign Large-size Research Facility Application Supporting project and the Global Science Experimental Data Hub Center of the Korea Institute of Science and Technology Information; the Polish Ministry of Science and Higher Education and the National Science Center; the Ministry of Education and Science of the Russian Federation and the Russian Foundation for Basic Research; the Slovenian Research Agency; Ikerbasque, Basque Foundation for Science and Ministry of Economy and Competitiveness (MINECO) (Juan de la Cierva), Spain; the Swiss National Science Foundation; the Ministry of Education and the Ministry of Science and Technology of Taiwan; and the United States Department of Energy and the National Science Foundation. This work is supported by a Grant-in-Aid for Scientific Research (S) “Probing New Physics with Tau-Lepton” (No. 26220706), and Grant-in-Aid for Scientific Research on Innovative Areas “Elucidation of New Hadrons with a Variety of Flavors”.
