Recombinant human soluble thrombomodulin prevents acute lung injury in a rat cardiopulmonary bypass model

Shingo Hirao, MD, Kenji Minakata, MD, PhD, Hidetoshi Masumoto, MD, PhD, Kazuhiro Yamazaki, MD, PhD, Tadashi Ikeda, MD, PhD, Kenji Minatoya, MD, PhD, and Ryuzo Sakata, MD, PhD

ABSTRACT

Background: Cardiopulmonary bypass (CPB) may induce systemic inflammatory responses causing acute lung injury. Recombinant human soluble thrombomodulin (rTM) is reported to attenuate the secretion of inflammatory cytokines and the high-mobility group box 1 (HMGB1) protein, which is critical in controlling systemic inflammation and apoptosis. We investigated the protective effects of rTM on CPB-induced lung injury in a rat model.

Methods: Eighteen male Sprague–Dawley rats were divided into 3 groups: sham, control (CPB alone), and rTM (CPB + rTM). CPB was conducted in the control group and the rTM group. A bolus of rTM (3 mg/kg) was administered to the rTM group rats before CPB establishment.

Results: The ratio of partial pressure of arterial oxygen to the fraction of inspired oxygen only dropped markedly from before CPB in the control group (P < .001). Serum tumor necrosis factor α, interleukin (IL) 6, and HMGB1 levels were significantly higher in the control group after CPB. Pathologic study revealed significantly more severe congestion, alveolar hemorrhage, neutrophil accumulation, and edema, and the number of lung cells expressing HMGB1 increased in the control group. The mRNA expression levels of tumor necrosis factor α, IL-6, IL-1β, and HMGB1 in the control group were significantly higher than those in other groups. According to Western blot analysis, nuclear factor-kB p65 in lung tissue was significantly downregulated in the rTM group. The number of apoptotic cells and the protein of cleaved Caspase-3 were reduced in the rTM group.

Conclusions: These results suggest that rTM prevents acute lung injury through attenuating inflammation and apoptosis during and after CPB in a rat model. (J Thorac Cardiovasc Surg 2017; :1-11)

Acute lung injury (ALI) induced by cardiopulmonary bypass (CPB), a common and serious complication in patients undergoing cardiac surgery with CPB, is an important factor influencing morbidity and mortality after surgery and is caused by the activation of several cellular immune systems from contact activation, ischemia-reperfusion injury, and endotoxemia. Acute respiratory distress syndrome (ARDS) is a rare but serious complication associated with significant mortality. The incidence and mortality of ARDS in patients undergoing CPB were reported to be 0.4% to 0.6% and 15% to 41.5%, respectively. Although various methods have

Central Message
Administration of recombinant human soluble thrombomodulin prevents cardiopulmonary bypass-related acute lung injury through attenuating inflammation and apoptosis.

Perspective
Administration of recombinant human soluble thrombomodulin may have protective effects on acute lung injury through inhibition of inflammation and apoptosis during and after cardiopulmonary bypass. It would be a novel prophylactic strategy to prevent cardiopulmonary bypass-related lung injury, which can be a lethal complication after cardiovascular surgery.
been proposed to protect organs from impaired situations, such as leukocyte-depleting filters; monoclonal anticytokine antibodies; and pharmacologic manipulations by corticosteroids, polymorphonuclear elastase inhibitors, or statins, only a few modalities are currently used in practice. High-mobility group box 1 (HMGB1), known as a danger-associated molecular pattern signal, acts as an important structural component in the chromatin complex to regulate gene transcription and to stabilize nucleosome formation. Once released from damaged cells, HMGB1 binds to the endothelial cell surface receptor, such as the receptor for advanced glycation end products (RAGE) or toll-like receptors, to trigger the activation of the downstream proinflammatory pathway and tissue damage. Furthermore, HMGB1 is reported to be a biomarker for preclinical detection of potential organ dysfunction such as leukocyte-depleting filters; monoclonal anticytokine antibodies; and pharmacologic manipulations by corticosteroids, polymorphonuclear elastase inhibitors, or statins, only a few modalities are currently used in practice.

**METHODS**

**Animals**

Eighteen male Sprague-Dawley rats (aged 11 weeks, 368-407 g body weight; CLEA Japan Inc, Tokyo, Japan) were used in this study. Before experimentation, all rats were given 1 week to acclimate. The animals in this study received humane care in compliance with the Principles of Laboratory Animal Care formulated by the National Society for Medical Research and the Guide for the Care and Use of Laboratory Animals prepared by the Institute of Laboratory Animal Resources and published by the National Institute of Health (www.nap.edu/catalog/5140.html).

**rTM**

rTM was generously provided by Asahi Kasei Pharma Co (Tokyo, Japan) and diluted with saline to a final concentration of 4.0 mg/mL before experiments.

**Experiment Protocols**

The rats were randomly assigned to 1 of the following 3 experimental groups (n = 6 for each group): sham group, control group of rats undergoing CPB, or rTM group of rats undergoing CPB that received a bolus of rTM (3 mg/kg) via the femoral vein 30 minutes before CPB (Figure 1, A).

**Surgical Procedure**

Each animal was initially anesthetized with 3.0% isoflurane-mixed air inhalation with a vaporizer. After the insertion of a 16-gauge cannula into the trachea, mechanical ventilation was performed during the entire experiment with 8 mL/kg tidal volume, a respiratory rate of 70 cycles per minute, and 30% of inspired oxygen fraction. Anesthesia was maintained with 1.5% to 2.0% isoflurane with an additional administration of 30 mg/kg intraperitoneal pentobarbital at CPB initiation. All subsequent procedures were performed under aseptic conditions.

CPB was performed using a surgical technique as previously described in our laboratory with some modifications (Video 1). 20, 21 The right femoral artery was cannulated with a 24-gauge intravenous catheter (SURFLO ETFE I.V. Catheter; Terumo, Tokyo, Japan) to monitor systemic arterial pressure and to analyze arterial blood gas (eopc Blood Analysis System; Alere Medical Co, Tokyo, Japan). After systemic administration of heparin sodium (500 IU/kg), the left femoral artery was cannulated with a 24-gauge intravenous catheter as an arterial infusion line for the CPB circuit. A 17-gauge multiorifice angiocatheter (Happy Cath 19-gauge inner diameter;
Medikit Co, Tokyo, Japan) was introduced into the right internal jugular vein and advanced into the right atrium and inferior vena cava. The CPB circuit was primed with approximately 11 mL of hydroxyethyl starch solution with 0.2 mL heparin and 0.5 mL 7% sodium bicarbonate solution (Hespander; Fresenius Kabi Japan, Tokyo, Japan). Blood was pumped from a venous reservoir through a modified neonatal membrane oxygenator (MERA, Tokyo, Japan) using a tubing roller pump (model RP-VT; Furue Science Co, Tokyo, Japan).

Normothermic CPB with a flow of 100 mL/kg/min was performed for 90 minutes. Furthermore, the TM group rats received a bolus of recombinant TM (3 mg/kg) via the femoral vein at 30 minutes before CPB establishment. CPB was terminated after 90 minutes without using any vasoactive agents, and the animals were ventilated for another 60 minutes. The remaining priming solution was gradually infused maintaining the mean arterial pressure at more than 70 mm Hg. In the sham group, the animals were cannulated and gradually infused with 11 mL CPB priming solution without conduction of CPB.

Arterial blood samples were collected just before CPB, 15 minutes after CPB initiation, immediately after, and 1 hour after the end of CPB. Hematocrit, hemoglobin concentration, pH, serum lactate, base excess, and partial pressure of arterial oxygen (PaO2) and partial pressure of arterial carbon dioxide were measured. Systemic arterial pressure was monitored continually during the experiments, and mean arterial pressure and heart rate were recorded. Rectal temperature was continuously monitored and maintained at 37°C by an electric mattress pad and a heat lamp placed over the animal and the CPB equipment. Four hours after the termination of CPB, all rats were euthanized under anesthesia. The lungs were collected bilaterally and divided into several parts.

**Ratio of Partial Pressure of Arterial Oxygen to Fraction of Inspired Oxygen (PF Ratio)**

PF ratio was calculated using the collected arterial blood samples before CPB, immediately after, and 1 hour after the end of CPB.
Measurement of Wet to Dry Weight Ratio of the Lung

The water content of the lung, representing the severity of pulmonary edema, was measured by calculating the wet to dry weight ratio of lung tissues. The left upper lung was weighed and dried on a heating device at 75°C for 72 hours to obtain the pulmonary ratio of wet to dry weight.

Measurement of Cytokines and HMGB1 Concentration

Fifteen minutes after CPB termination, blood samples were collected and centrifuged at 3000 rpm for 20 minutes at 4°C and the serum was obtained. Concentrations of interleukin (IL) 6, tumor necrosis factor-α (TNF-α), and HMGB1 were assayed by the enzyme-linked immunosorbent assay sandwich method. Serum levels of IL-6 (R&D Systems Inc, Minneapolis, Minn), TNF-α (R&D Systems Inc), and HMGB1 (ShinoTest Corporation, Tokyo, Japan) were measured using a commercial enzyme-linked immunosorbent assay kit according to the manufacturer’s protocols. The values of absorbance were measured with a microplate reader (Bio-Rad Laboratories Inc, Hercules, Calif) at 450 nm for HMGB1 or at 450 nm with a subtract reading at 540 nm for IL-6 and TNF-α.

Immunohistochemical Staining

Immunohistochemical staining was performed on paraffin-embedded sections with an antibody specific for HMGB1 (Abcam, ab18256) and cleaved Caspase-3 (Cell Signaling Technology, Asp175). Deparaffinized sections were incubated overnight at 4°C with a primary antibody for HMGB1 (1:3000) and cleaved Caspase-3 (1:400). Subsequently, sections were incubated at room temperature for 45 minutes in a solution with an antirabbit immunoglobulin G secondary antibody (Nichirei, Tokyo, Japan). The sections were stained with horseradish peroxidase and visualized with diaminobenzidine. Then, a mean score for each parameter was calculated.

Histologic Analysis

The lungs were obtained from animals 4 hours after CPB, fixed in 4% phosphate-buffered paraformaldehyde, embedded in paraffin, cut into 4-μm sections, and then stained with hematoxylin and eosin. Images were photographed using an all-in-one digital microscope (BIOREVO BZ-9000; Keyence, Osaka, Japan) and assessed using the BZ-X Analyzer (Keyence) software. The extent of lung injury was evaluated by a previously described technique. Twenty-four areas of lung tissue were graded in a blinded manner on a scale of 0 to 4 (0 = abnormalities absent and tissue seems normal, 1 = light, 2 = moderate, 3 = strong, and 4 = intense) for the degree of congestion, edema, inflammation, and hemorrhage. Then, a mean score for each parameter was calculated.

Quantitative Real-Time Polymerase Chain Reaction

The total RNAs were isolated from frozen tissues of the right lung using an RNasey mini kit (Qiagen, Hilden, Germany). The obtained RNA was reverse-transcribed into complementary DNA using the Invitrogen SuperScript III First-Standard Synthesis SuperMix for Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR) (Life Technologies, Carlsbad, Calif), in accordance with the manufacturer’s instructions. The qRT-PCR procedure was performed as follows: 95°C for 10 minutes; 40 cycles at 95°C for 15 seconds, and 60°C for 60 seconds. Levels of messenger RNA (mRNA) were conducted on an Applied Biosystems StepOnePlus Real Time PCR System (ThermoFisher Scientific, Waltham, Mass) by using a Thunderbird Sybr qPCR Mix (TOYOBO, Osaka, Japan). Expression levels for each mRNA were normalized to the mRNA level of the housekeeping gene glyceraldehyde 3-phosphate dehydrogenase. The relative mRNA expression level was calculated using the comparative threshold cycle method. Specific primers were designed as shown in Table E1.

RESULTS Physiologic Data During and After CPB

All rats survived during the CPB procedures and for 4 hours after the operation. The physiologic data during the operation are summarized in Table 1 and Table E2. The preoperative data were comparable in the 3 groups.
Throughout the operation, heart rate and mean arterial pressure were stable in all 3 groups. The rectal temperature and hemoglobin level decreased in the control and rTM groups because of hemodilution caused by the priming volume. Conversely, the PaO₂ in these groups increased during CPB due to membrane oxygenation. These data indicate successful CPB running through the circuit.

**PF Ratio and Wet to Dry Ratio of the Lung**

The PF ratio for each group both at and 1 hour after CPB were compared with the baseline (Figure 1, B). Although the ratio in the control group significantly decreased at and 1 hour after CPB (539.7 ± 63.7 to 449.5 ± 69.4 and 390.0 ± 80.2; \(P = .027\) and \(P < .001\), respectively), the ratios in the sham and rTM groups were maintained. The lung wet to dry weight ratio in the control group was significantly higher than those in the sham and rTM groups (5.11 ± 0.45 [control] vs 4.05 ± 0.54 [sham], 4.36 ± 0.27 [rTM]; \(P = .002\) and \(P = .023\), respectively) (Figure 1, C). These results indicate that rTM administration rescued pulmonary dysfunction mediated by overhydration during and after CPB.

**Histologic Analysis of the Lung**

The extent of lung damage in each group assessed by histologic analyses is shown in Figure 2, A-C. For interstitial

![Histologic Analysis](image-url)
edema, inflammatory cell infiltration, and hemorrhage, a significant difference was observed in the control group (Figure 2, B). However, the pathologic findings were markedly reduced in the rTM group compared with those in the control group (Figure 2, C). Furthermore, all histologic scoring data were significantly decreased in the rTM group compared with the control group (0.98 ± 0.38 vs 2.37 ± 0.4 [congestion], 1.22 ± 0.34 vs 3.00 ± 0.24 [edema], 1.06 ± 0.34 vs 2.85 ± 0.18 [inflammation], and 1.29 ± 0.25 vs 2.33 ± 0.32 [hemorrhage]; P < .001 in each parameter) (Figure 2, D). These results indicate that the rTM administration protected lung tissue from CPB-related lung damage.

**Systemic and Local Lung Inflammatory Responses Associated with HMGB1**

In the present experiment, the serum concentration of TNF-α, IL-6, and HMGB1 peaked at the end of CPB. The serum levels of each are shown in Figure 3, A-C. Serum concentrations of TNF-α, IL-6, and HMGB1 were significantly higher in the control group than in the sham group (2542 ± 2259 vs 277 ± 344 [TNF-α], 2379 ± 809 vs 569 ± 498 [IL-6], and 8.76 ± 4.87 vs 1.74 ± 0.58 [HMGB1]; P = .027, .002, .002, respectively) and significantly lower in the rTM group than in the control group (187 ± 426 vs 2542 ± 2259 [TNF-α], 476 ± 903 vs 569 ± 498 [IL-6], and 1.22 ± 0.34 vs 2.37 ± 0.18 [HMGB1]; P < .05, .01, and .01, respectively).
vs 2379 ± 809 [IL-6], and 3.09 ± 0.92 vs 8.76 ± 4.87 [HMGB1]; P = .002, .021, and .01, respectively).

The mRNA expression levels of TNF-α, IL-6, and IL-1β in the lung were significantly reduced compared with the control group (0.044 ± 0.011 vs 0.247 ± 0.165 [TNF-α], 0.0062 ± 0.0089 vs 0.0226 ± 0.0139 [IL-6], and 0.032 ± 0.014 vs 0.083 ± 0.032 [IL-1β]; P = .005, .029, and .006, respectively) (Figure 3, D-F). There was a significant increase in the mRNA expression level of HMGB1 in lung tissue in the control group compared with the sham group (1.07 ± 0.51 vs 0.40 ± 0.09; P = .004) (Figure 3, G). However, mRNA expression of HMGB1 was significantly reduced in the rTM group compared with the control group (0.36 ± 0.08 vs 1.07 ± 0.51; P = .003). Immunohistochemical analysis revealed that the number of lung cells expressing cytoplasmic HMGB1 increased only in the control group (Figure 4, A-C). In contrast, the number of lung cells expressing HMGB1 was dramatically reduced in the rTM group compared with the control group (38.0 ± 8.1 vs 127.5 ± 40.1; P < .001) (Figure 4, D).

The mRNA expression level of NF-κB p65 in the lung was significantly reduced in the rTM group compared with the control group (0.046 ± 0.005 vs 0.060 ± 0.009; P = .003). Furthermore, concerning the Western blotting analysis, the protein level of NF-κB p65 was also significantly reduced in the rTM group compared with the control group (0.22 ± 0.34 vs 0.66 ± 0.23; P = .027) (Figure 3, I). These results indicate that HMGB1 is associated with CPB-related systemic and local lung inflammatory responses, and administration of rTM suppresses the inflammation.

**Apoptosis in the Lung**

TUNEL assay for lung tissue is shown in Figure 5, A-C. The number of TUNEL-positive cells in the rTM group was significantly less than in the control group (43.8 ± 34.2 vs 110.7 ± 59.5; P = .037) (Figure 5, G). Additionally, immunohistochemical analysis revealed that the number of lung cells expressing cleaved Caspase-3 increased only in the control group (Figure 5, D-F). In contrast, the number of lung cells expressing cleaved Caspase-3 was dramatically reduced in the rTM group compared with the control group (208.0 ± 70.5 vs 404.0 ± 113.3; P < .001) (Figure 5, H). The extent of the mRNA level of Caspase-3 and Bcl-2-associated X protein was significantly attenuated in the rTM group (0.012 ± 0.002 vs 0.31 ± 0.007 [Caspase-3] and 0.075 ± 0.008 vs 0.133 ± 0.028 [Bcl-2-associated X protein]; P < .001 in each case) (Figure 5, I and J). Likewise, the protein expression of cleaved Caspase-3 on the Western blotting analysis was also suppressed in the rTM group compared with the control group (0.20 ± 0.06 vs 0.36 ± 0.17; P = .027) (Figure 5, K).

These results indicate that rTM administration mitigates apoptosis in the lung mediated by CPB.

DISCUSSION

In the present study, we tried to determine whether an rTM treatment possesses protective effects on a CPB-induced lung injury. The results demonstrated that the administration of rTM before undergoing CPB was associated with a significant reduction of systemic inflammatory responses and local lung inflammation, which led to protection against lung injury. Our results also suggested that the administration of rTM attenuated systemic HMGB1 concentration and HMGB1 activity in the lung, which might have attenuated exacerbation of inflammatory responses. In addition, rTM attenuated CPB-related apoptosis in the lung.

HMGB1 is an important structural component of the chromatin complex, which shapes the nucleosomal structure and is involved in various processes such as DNA binding, replication, repair and bending, and gene transcription and stability.7,23 Under stressed conditions, HMGB1 can be actively released from immune cells and passively released from necrotic or damaged cells.24 Secreted HMGB1 binds to RAGE and/or innate toll-like receptor 2 and 4 and, subsequently, activates signal cascades, which results in further downstream inflammatory cytokine release, establishing a vicious inflammatory cycle.8,25 TM binds to HMGB1 by its D1 domain and interferes with the binding of HMGB1 to RAGE,14 which results in decreased proinflammatory activity of HMGB1. TM also plays an important role in the degradation of HMGB1.26 These molecular and biophysical characteristics of TM encouraged us to verify the anti-inflammatory effect of TM against CPB-related inflammatory lung injury, which is potentially related to the activation of HMGB1.

We demonstrated that the administration of rTM dramatically reduced the serum and lung expression levels of HMGB1, inflammatory cytokines, and NF-κB, a key transcription factor regulating the inflammatory responses27 in our rat CPB model. We analyzed the concentrations of the inflammatory biomarkers within a short period of time from the cessation of CPB based on previous reports indicating that those markers rapidly alleviate after the inflammatory stimulus in rat models,18,28,29 and successfully demonstrated the effect of rTM on the attenuation of CPB-related inflammation. Based on previous clinical studies, the serum secretion of HMGB1 level is elevated in patients undergoing cardiac surgery,10,30 and a recent clinical study showed that the peak serum HMGB1 level during CPB was associated with more severe systemic inflammatory response syndrome and a higher incidence of lung oxygenation impairment after CPB.10 Additionally, the serum HMGB1 level is an independent biomarker for predicting intensive care unit mortality in patients with severe pneumonia and ARDS.31 In the present study, the serum HMGB1 level after 90 minutes of CPB in the control group was comparable with the values in reported clinical studies,10,30 indicating that we could successfully simulate severe CPB-related ARDS associated with HMGB1 activation in our rat CPB model and show the

FIGURE 6. Putative mechanisms of recombinant human thrombomodulin (rTM) on cardiopulmonary bypass (CPB)-related lung injury in this study. Putative mechanisms for how administration of rTM prevents lung injury induced by CPB. Green arrows indicate tentative effects of rTM administration. advantageous effect of TM against the inflammation, which may fairly be relevant in clinical settings.

The pathophysiology of ARDS is characterized by complex mechanisms, including inflammation and apoptosis. Epithelial cell apoptosis is considered to be fundamentally associated with the pathogenesis of ALI and ARDS in humans. One of the antiapoptotic effects of rTM is mediated by the activation of protein C and PAR-1 and downregulation of Bcl-2-associated X protein, which stimulates the release of promoters of apoptosis such as cytochrome c and Caspase-3. Furthermore, suppression of inflammatory cytokines such as TNF-α mitigates the extrinsic apoptotic pathway mediated by cell surface death receptors belonging to the tumor necrosis factor-receptor family, which accelerates cleavage and activation of Caspase-3. In the present study, rTM showed an antiapoptotic effect on lung injury, which may potentially be mediated by a direct mechanism through PAR-1 activation and the extrinsic pathway related to suppression of inflammatory cytokines. The proposed mechanism as to how rTM may attenuate the ALI induced by CPB is summarized in Figure 6.

The present study includes several limitations. First, we did not investigate the appropriate dose, dose-dependent effect, and the administration timing of rTM. A previous study administering the same dose of rTM in a lipopolysaccharide-induced rat lung injury model, demonstrated the attenuation of lung injury, which allowed us to refer this concentration to our study. However, the situation, extent, and/or timing of the inflammatory change may be different from our study considering the divergence of inflammatory mediators, and a closer investigation of the appropriate dose is vital before proceeding with clinical trials. Second, we did not investigate the influence or aggregate effects of rTM for surgical bleeding during cardiac surgery using CPB. Nonetheless, a phase III trial using rTM with a low dose of heparin in DIC patients did not increase the incidents of bleeding, and we should be aware of the risk of surgical bleeding considering the use of TM in combination with a high dose of heparin sodium, which is commonly used for anticoagulation during CPB in preclinical large-animal experiments. Finally, potential differences in immune systems between humans and rodents, and clinical settings, such as the use of exogenous blood products that influence the extent of hemodilution, have not been examined and should be further investigated.

CONCLUSIONS

rTM may attenuate ALI through inhibition of systemic and local lung inflammation during and after CPB in a rat model. The present study may provide the key for a novel strategy to prevent lung injury induced by CPB, which should be validated by preclinical and clinical trials.

Conflict of Interest Statement

Authors have nothing to disclose with regard to commercial support.

The authors thank Dr M. Funamoto for providing technical support, Mr S. Miyake for providing expert technical assistance, and Asahi Kasei Pharma for providing the recombinant human soluble thrombomodulin.

</table>

The values of blood gas analyses of T-CPB are the mean values of 2 points when undergoing CPB. PaO2, Partial pressure of arterial oxygen; PaCO2, partial pressure of arterial carbon dioxide; T-Pre, time before CPB; T-CPB, time when undergoing cardiopulmonary bypass; T-Post, 1 hour after CPB; rTM, recombinant human soluble thrombomodulin.

*P < .05 versus sham. †P < .01 versus sham. ‡P < .001 versus sham.
Recombinant human soluble thrombomodulin prevents acute lung injury in a rat cardiopulmonary bypass model

Shingo Hirao, MD, Kenji Minakata, MD, PhD, Hidetoshi Masumoto, MD, PhD, Kazuhiro Yamazaki, MD, PhD, Tadashi Ikeda, MD, PhD, Kenji Minatoya, MD, PhD, and Ryuzo Sakata, MD, PhD, Kyoto, Japan

Administration of recombinant human soluble thrombomodulin prevents cardiopulmonary bypass-related acute lung injury through attenuating inflammation and apoptosis.
