8 **ABSTRACT:** Communesins, isolated from the mycelium of a strain of *Penicillium* sp., are cytotoxic
9 heptacyclic indole alkaloids bearing a bis-aminal structure and two contiguous quaternary carbon
10 centers. Towards a total synthesis of communesin F, we synthesized a pentacyclic ABCDG ring
11 skeleton via carboborylation of 1,3-diene and a Friedel-Crafts-type cyclization, resulting in the
12 formation of an azepine ring through a Bi(OTf)₃-catalyzed S_N2' reaction.

16 Introduction

Communesins A and B, which were originally isolated by Numata and co-workers from the mycelium of a strain of *Penicillium* sp. attached to the marine alga *Enteromorpha intestinalis*, are heptacyclic indole alkaloids (Figure 1).¹ Spectroscopic analyses, including nuclear magnetic resonance (NMR) spectroscopy (¹H NMR, ¹³C NMR including 2D NMR) and high-resolution mass spectrometry, have revealed that their structures are quite unique. They are characterized by a heptacyclic skeleton bearing two amines and two contiguous quaternary carbon centers. To date, nine congeners have been reported,^{2–6} and perophoramidine is also known as a structurally related bis-amidine indole alkaloid.⁷ Recently, Tang and co-workers confirmed that communesins can be biosynthetically produced through the coupling of aurantioclavine and tryptamine based on genetic inactivation studies.⁸ Communesins show cytotoxicity against P388 lymphocytic leukemia cells (ED₅₀ A: 3.5 µg/mL, B: 0.45 µg/mL) and potent insecticidal activity towards silkworms (LD₅₀ D: 300 µg/g, E: 80 µg/g). Because of their unique structure and biological activity, many research groups have conducted synthetic studies of communesins in which various synthetic methods were developed.^{9–14} The first racemic total synthesis of communesin F was achieved by Qin and co-workers based on an intramolecular cyclopropanation strategy.¹⁵ Weinreb and Funk also reported total synthesis of communesin F, independently.^{16,17} The first asymmetric total syntheses of communesins A, B and F were accomplished by Ma and co-workers.^{18,19} Asymmetric total syntheses were also reported by Stoltz, Movassaghi, Yang, and Chen, independently.^{20–23} We have also engaged in the development of synthetic strategies for this class of alkaloids including communesins, perophoramidine and aurantioclavin.^{24–31}

36 Results and Discussion

37 Recently, we have developed palladium(Pd)-catalyzed carbosilylation of 1,3-diene with carbamoyl chloride for the
38 synthesis of several spirooxindoles.³² Extending this reaction, a Pd-catalyzed carboborylation of 1,3-diene was
39 developed for a synthesis of iminoindoline.³⁰ Considering our developed method, it was envisioned that communesin
40 F would be accessed from a pentacyclic skeleton **II** through intermediate **I** by the introduction of an aminoethyl unit
41 and the formation of amidine. The pentacyclic skeleton **II** would be constructed from a tetracyclic compound **IV** via
42 **III** by the introduction of an allyl alcohol unit, resulting in an S_N2' reaction for the formation of an azepine ring and
43 a reduction of amidine. The tetracyclic compound **IV** can be synthesized by a carboborylation of 1,3-diene **VI** and
44 an intramolecular Friedel-Crafts-type reaction of a resultant iminoindoline **V**.³⁰ Following this retrosynthetic analysis,
45 we have recently succeeded in the construction of tetracyclic skeleton **IV** (R = OMe) from diene **VI** (R = OMe)
46 through iminoindoline **V** (R = OMe). However, compound **1** could not be converted to compound **2** through removal
47 of the methyl group, although we tried various conditions including BBr₃, BCl₃, AlCl₃, LiCl, Ph₂PLi and
48 *p*MeC₆H₄SLi (Scheme 1b).³³ These reaction conditions resulted in the removal of a Cbz group or the decomposition
49 of compound **1**. Therefore, we needed to revise our initial synthetic route and planned to employ a 1,3-diene-
50 containing triflate (R = OTf) to avoid a protecting group manipulation. The use of a substrate bearing a triflate group
51 for Pd-catalyzed carboborylation would extend its reaction scope, and it might react itself under the reaction
52 conditions. In the current manuscript, we report the construction of a pentacyclic skeleton of communesin F by
53 extending our strategy based on carboborylation of 1,3-diene.

(a) Retrosynthesis of communesin F

(b)

Scheme 1. (a) Retrosynthesis of communesin F and (b) failed attempt at removing a methyl group from compound 1.

The synthesis started with a removal of a methyl group on a phenolic hydroxyl group. A methoxy aniline derivative **3**, which was prepared from *t*-butyl(3-methoxyphenyl)carbamate in four steps,³⁰ was treated using BBr_3 to give a phenol (Scheme 2). The resultant phenolic hydroxy group was silylated with *tert*-butyldimethylsilyl (TBS) chloride and imidazole to give compound **4**. A half reduction of a lactone with diisobutylaluminum hydride (DIBAL-H) was followed by Wittig olefination, which gave diene **5** through internal transfer of a TBS group. After the formation of urea by a treatment of phenyl isocyanate, a phenolic hydroxy group was protected as a triflate. A removal of a TBS group was followed by a Mitsunobu reaction with $pNsNHBoc$ ³⁴ to give compound **8**, which was converted to carbodiimide **9** through dehydration with CBR_4 , PPh_3 and Et_3N .

With carbodiimide **9** containing a diene moiety, we investigated whether the triflate is intact under the reaction conditions of Pd-catalyzed carboborylation of 1,3-diene. In the previous literature, there is no report concerning

69 Pd(II)-catalyzed Miyaura borylation of triflates and diborane without a ligand, but reactions using
70 diphenylphosphinoferrocene³⁵ or the reaction of arylbromide have been reported.³⁶ Therefore, it was expected that a
71 triflate group would be intact during the carboborylation of 1,3-diene. As expected, the reaction of **9** proceeded
72 smoothly under the established conditions (Pd(OAc)₂, (pinB)₂, xylene, 50°C) to give an allyl borane, which was
73 treated with NaBO₃·4H₂O to give allyl alcohol **10**. After silylation of allyl alcohol **10**, a *tert*-butoxyoxycarbonyl (Boc)
74 group was introduced to an amidine nitrogen for further transformation. The treatment of compound **11** using
75 tetrabutylammonium fluoride gave an allyl alcohol along with the removal of a triflate group, which was converted
76 to allyl bromide **12** under standard conditions. Unfortunately, the resultant allyl bromide **12** could not be converted
77 to compound **13** through a treatment of Tf₂O and pyridine. On the other hand, when HF·pyridine was used, a
78 triethylsilyl group was selectively removed with the triflate group intact. The resultant allyl alcohol was also
79 converted to allyl bromide **13** containing a triflate group, while a small amount of compound **14** was also obtained
80 through the removal of a Boc group.

and its derivatization.

Next, we investigated Friedel-Crafts-type cyclization of allyl bromides **12** and **13** to construct a tetracyclic ABCD ring skeleton. Previously, we have reported the cyclization of compound **15** containing a methoxy group using 10 mol% of Bi(OTf)₃ and 3.5 equivalents of AgOTf (Table 1, entry 1).^{30,37–39} The reaction gave compound **16a** in 49% yield along with **16b** in 30% yield. We initially applied these conditions to a cyclization of compound **13** containing a triflate group. However, the reaction gave a complex mixture instead of any cyclized products **17a** and **17b** (entry 2). On the other hand, the cyclization of compound **12** containing a phenolic hydroxy group proceeded under the same conditions to give compounds **18a** and **18b** in 63% and 30% yields with excellent stereochemistry, respectively (entry 3). The stereochemistry was determined by a comparison with our previous results³⁰ and a NOESY experiment of a derivatized compound **28** (Scheme 4, *vide infra*). When 3.5 equivalents of AgOTf was reduced to 1.2 equivalents, the formation of byproduct **18b** was suppressed to 17% yield (entry 4). Finally, the yield of the desired product **18a** was improved to 80% yield using 1.05 equivalents of AgOTf (entry 5). AgOTf was essential for this Friedel-Crafts-type reaction (entry 6)

Table 1. Formation of a tetracyclic ABCD skeleton through a Friedel-Crafts-type reaction.

After the construction of a tetracyclic ABCD ring skeleton containing an amidine, we turned our attention to the

formation of an azepine ring (G ring). A treatment of compound **18a** with TiF_2O and pyridine gave compound **17a** in 91% yield (Scheme 3). To introduce an allyl alcohol unit, Suzuki-Miyaura coupling with vinyl boronic ester **19** was examined. When compound **17a** and vinyl boronic ester **19** were treated with a catalytic amount of $\text{Pd}(\text{dba})_2$, SPhos and K_3PO_4 , or $\text{Pd}(\text{PPh}_3)_4$ and Na_2CO_3 in *N,N*-dimethylformamide (DMF) at 100°C , respectively, these reactions gave the desired product **20** in low yields (Table 2, entries 1 and 2). However, conditions involving $\text{Pd}(\text{PPh}_3)_4$ and Na_2CO_3 in toluene and ethanol at 100°C improved the yield to 56% (entry 3). The removal of the *p*Ns and trimethylsilyl (TMS) group gave allyl alcohol **21** in 66% yield over two steps. To construct the azepine ring, mesylation of a tertiary alcohol was initially attempted through a treatment using methanesulfonyl chloride (MsCl) and Et_3N .¹⁸ However, a dehydration occurred to give diene **23** instead of the desired cyclized product **22**. Interestingly, when compound **21** was treated with pyridinium *p*-toluenesulfonate (PPTS),¹⁵ ortho-amide **24** was observed (as assessed using ^1H NMR analysis). A related structure was observed in synthetic studies of dehaloperophoramidine reported by Somfai and co-workers.^{13,14} We considered the thermodynamic stability of possible equilibrium products such as simplified compounds **25**, **26** and **27** through density functional theory (DFT) calculations (Figure 2). These calculations revealed that ortho-amide **26** was the most stable isomer among these compounds. These results indicate that the formation of the ortho-amide through acid activation using PPTS from amidine would be a competitive process with the formation of the azepine ring via the $\text{S}_{\text{N}}2$ reaction of the tertiary alcohol, and the equilibrium tends to be biased towards the ortho-amides such as compounds **24** and **26**. Therefore, we expected that it would be difficult to achieve the formation of azepine **22** from compound **21** containing the amidine moiety.

Therefore, a reduction of amidine **20** was investigated prior to the formation of the azepine ring to avoid the formation of the ortho-amide (Scheme 4). When compound **20** was treated using NaBH₄, the desired product was not obtained. In the case of DIBAL-H, the removal of a Boc group occurred instead of the reduction of the amidine. However, in sharp contrast, treatment using catecholborane⁴⁰ gave the desired product **28** in 65% yield as a 3.3:1 mixture of diastereomers. A NOESY experiment indicated that the stereochemistry of the major isomer was a *trans*-fused structure, which would be epimerized to a *cis*-fused structure later. Because a reducing reagent approached from the less hindered face, the *trans* isomer was obtained as a major product in this reaction. After the removal of Boc and the TMS groups, the formation of an azepine ring was investigated again. When compound **29** was treated using MsCl and Et₃N,¹⁸ the reaction gave diene **31** in 48% yield and the desired cyclized product **30** was not detected at all (Table 3, entry 1). When Bi(OTf)₃ was employed at −15°C as a Lewis acid, the reaction proceeded to give the desired product **30** as a major product albeit in low yield (entry 2).^{41,42} The reaction using Bi(OTf)₃ at −40°C gave the desired product **30** in 17% yield with recovery of the starting material (entry 3). However, under room temperature reaction

conditions the starting material **29** was consumed completely to give the desired azepine **30** in 55% yield, while diene **31** was obtained in 34% yield (entry 4). The obtained pentacyclic compound **30** would be useful for further derivatization, and now we are investigating further transformations to achieve a total synthesis of communesin F.

In summary, we have investigated the synthesis of a pentacyclic ABCDG ring skeleton of communesin F based on carboborylation of 1,3-diene, a Bi(OTf)₃-catalyzed Friedel-Crafts-type reaction and azepine ring formation. It is interesting that a triflate group was intact under the conditions required for Pd-catalyzed carboborylation of 1,3-diene. Additionally, it was essential that the resultant amidine was reduced prior to the formation of the azepine ring through Bi(OTf)₃-catalyzed cyclization to avoid an undesired formation of ortho-amide. We are currently investigating further transformation of the pentacyclic compound to complete the synthesis of communesin F.

Experimental Procedure

General. All non-aqueous reactions were carried out under a positive pressure of argon in over-dried glassware. Analytical thin-layer chromatography was performed using Silica gel 60 plates (Merck, Darmstadt, Germany). Silica gel column chromatography was performed using Kanto silica gel 60 (particle size 63–210 μm , Kanto, Tokyo, Japan) and Chromatorex BW-300 (Fuji silysia, Aichi, Japan). Proton nuclear magnetic resonance (^1H NMR) spectra were recorded using a JNM-ECA 500 (JEOL, Tokyo, Japan) at 500 MHz or a JNM-AL 400 (JEOL) at 400 MHz. Chemical shifts were reported relative to Me_4Si (δ 0.00) in CDCl_3 or the residual solvent peak in C_6D_6 (δ 7.16). Multiplicity was indicated by one or more of the following: s (singlet); d (doublet); t (triplet); q (quartet); m (multiplet); br (broad). Carbon nuclear magnetic resonance (^{13}C NMR) spectra were recorded using a JNM-ECA 500 at 126 MHz or a JNM-AL 400 at 100 MHz. Chemical shifts were reported relative to CDCl_3 (δ 77.0) or C_6D_6 (δ 128.0). Infrared spectra were recorded using a FT/IR-4100 Fourier-transform infrared spectrometer (JASCO, Tokyo, Japan) with ATR (attenuated total reflectance). Low and high resolution mass spectra were recorded using a JMS-700 mass spectrometer (JEOL) for FAB-MS and a LCMS-IT-TOF (Shimadzu, Kyoto, Japan) for ESI-MS.
